MODIFICATION TO MATH MODEL FOR  
SMALL INDEPENDENT ACTION FORCES (SIAF)  
FINAL REPORT

15 December 1973

Contract Number DAAH01-73-C-0914

Sponsored by:

U.S. Army Infantry School  
Concepts and Studies Division ACN 13954

Supported by ARPA Funds

Technical Requirement Number 1816

Amount of Contract: \$187,003

Contract Dates: 25 May 1973 to 31 December 1973

Prepared by:

System Group of TRW, Inc  
One Space Park  
Redondo Beach, California 90278

The research was the responsibility of the U.S. Army Infantry School, ACN: 13954. It was supported by funds from the Defense Advanced Research Projects Agency of the Department of Defense. Fiscal aspects of the contract were monitored by the U.S. Army Missile Command.

The views and conclusions contained in this document are those of the authors and should not be interpreted as necessarily representing the official policies, either expressed or implied, of the U.S. Army Infantry School or the U.S. Government.

## **REPRODUCTION QUALITY NOTICE**

**This document is the best quality available. The copy furnished to DTIC contained pages that may have the following quality problems:**

- **Pages smaller or larger than normal.**
- **Pages with background color or light colored printing.**
- **Pages with small type or poor printing; and or**
- **Pages with continuous tone material or color photographs.**

**Due to various output media available these conditions may or may not cause poor legibility in the microfiche or hardcopy output you receive.**

☐ **If this block is checked, the copy furnished to DTIC contained pages with color printing, that when reproduced in Black and White, may change detail of the original copy.**

ACKNOWLEDGEMENTS

The TRW Study Team consisted of the following members:

Project Management

J. C. Seaquist

Systems Analysis, Model Development, and Computer Programming  
(Including User's Manual Preparation)

R. Y. Cho

E. J. Criner

D. Rothman

J. Smit

L. B. Walters

T. C. Wong

A. W. Dobiesk - Department Manager

C. B. Whaley - Section Head

P. E. Groth - Report and User's Manual Preparation

The TRW Study Team wishes to acknowledge its appreciation to the Study Sponsor Representative, Major Ardeen R. Foss, U.S. Army Infantry School, to the Chairman of the Study Advisory Group, Colonel John E. McCleary, U.S. Army Infantry School, to his staff, and to the members and alternate members of the Study Advisory Group, for their guidance.

MODIFICATION TO MATH MODEL FOR SMALL INDEPENDENT ACTION  
FORCES (SIAF) FINAL REPORT

INTRODUCTION

This document, prepared by TRW Systems Group, One Space Park, Redondo Beach, California, constitutes the final technical report on the "Modification to Math Model for SIAF" program. This program was conducted under ARPA/AMICOM Contract Number DAAH01-73-C-0914 during the period 25 May 1973 to 31 December 1973. The original study sponsor was the USACDC Systems Analysis Group. Shortly after the start of the work, cognizance was transferred to the U. S. Army Infantry School. The principal product of this program was a revision to a computerized simulation model of a SIAF operating in both reconnaissances and combat modes developed by TRW under previous ARPA contracts.

The SIAF simulation model is provided as computer software installed on the CDC 6500 computer at Fort Leavenworth, Kansas, and additions to and replacements for a six-volume User's Manual as follows:

Volume I-Model Description and Programming Guide (This Final Report serves as a forward to Volume I)

Volume II-Model Subroutines (Terrain, Weather, Targets)

Volume III-Model Subroutines (SIAF Function and Ancillary Routines)

Volume IV-Model Program Listing

Volume V-Combat Initialization Subroutines

Volume VI-Combat Execution Subroutines

These six volumes are to be considered as part of the final report.

This final report provides a background to the SIAF program, a brief description of the features of the integrated SIAF model, and a summary of the tasks performed during the current contract.

Section 2 of Volume I provides a more complete overview of the SIAF model. Full details of the individual submodels are provided in Volumes II through VI.

## BACKGROUND

In recognition of the increasing importance and complexity of small military patrols in low intensity guerilla warfare, ARPA activated the Small Independent Action Forces (SIAF) program in 1968. This continued project has as its ultimate objective the improvement of the operational effectiveness of SIAF units. One aspect of this objective has been the need to develop a rapid and economical means of measuring patrol effectiveness to permit the effects of postulated improvements or changes to be evaluated. Namely, a capability is required to

- ° Study effects of changes in equipment
- ° Establish tradeoffs for organization/equipment mixes
- ° Expose alternative doctrine options

In furtherance of this objective, ARPA has sponsored several types of research and development programs. These have included the collection of extensive field data on the various aspects of patrol operations in Southeast Asia, equipment development programs, field test programs, and a SIAF computer model simulation program by TRW Systems. The model is the subject of this report.

The SIAF simulation model has been developed by TRW Systems under seven successive programs. The first, under ARPA/AMICOM Contract DAAH01-70-C-0141 running from August 1969 to June 1970, was to determine the feasibility of structuring a SIAF model for use as an evaluation tool. The second, under ARPA/AMICOM Contract DAAH01-71-C-0100 running from August 1970 to August 1971 was to develop a computerized simulation of a SIAF patrol in a reconnaissance role. The primary effort was formulation and programming of the model itself. Volumes II and III of the SIAF Users Manual describe primarily the results of that effort.

The third TRW SIAF program was the SIAF External Fire Support Study, under ARPA/AMICOM Contract DAAH01-71-C-1115 running from May 1971 to May 1972. An output of that study was an External Fire Support Submodel that was incorporated into the SIAF Reconnaissance Model.

The fourth SIAF model development program provided for the development and programming of a fully computerized stochastic combat submodel

which provided dynamic deployment logic as well as fully simulated small arms fire. This work was performed under ARPA/AMICOM Contract DAAH01-72-C-0305 running from November 1971 to December 1972. The results were fully integrated with the previous SIAF Reconnaissance Model.

Two subsequent contracts, DAAH01-73-C-0222 and DAAH01-73-C-0257 which were performed in December 1972 and from March 1973 to July 1973, respectively, were used to reprogram the SIAF model to run on the CDC 6500 computer.

The final SIAF model development contract was used to modify the SIAF Model. This has been performed under Contract DAAH01-73-C-0914 from June 1973 to December 1973. The work performed is the subject of this report.

#### MODEL SUMMARY

The Small Independent Action Forces (SIAF) Model is a computer simulation intended for use in evaluating the effectiveness of alternative SIAF concepts. The model essentially accepts as input a military operations plan, such as would be prepared by a military commander in the field for an actual patrol operation, and simulates this operation on a computer. It considers both reconnaissance and combat missions. The SIAF Model simulates the interactions of the operations plan with the terrain, weather, and enemy situation. It considers a total mission from beginning to end. The output of the model is the effectiveness of the particular operation under consideration. During the simulation of activities and events which occur during SIAF operations, the model calculates statistics pertaining to movement, navigation, surveillance and detection, fire support, supply maintenance, human maintenance, communications, and casualties.

The model is checked out and is ready for use. It can be applied to a variety of problems involving the effectiveness of SIAF operations, such as the effects of postulated improvements and determination of performance capabilities of these type units. It can also be used to study the sensitivities with respect to numerous input variables.

Listed below are some of the features of the SIAF model compared to other models which might be used for the same purpose:

- 1) It simulates the entire mission from start to finish and is capable of considering up to 10-day missions. This differs from many existing models of patrol operation which consider only a partial mission segment. The functions of movement, navigation, surveillance and detection, fire support, supply maintenance, human maintenance and external communications and their interactions are explicitly considered in the model.
- 2) It includes a detailed and realistic treatment of terrain considering relief, vegetation, obstacles, cultural features and surface material. This differs from other existing models in that for this model relief is represented by a continuous surface, and vegetation is represented throughout the entire area of operations instead of just locally.
- 3) It has an explicit detailed treatment of visual detection considering instantaneous locations of each SIAF and target individual as well as light level, reflectivity and background.
- 4) It includes dynamic movement of the patrol and detailed target movement. The patrols can advance toward targets or can be made to move around them.
- 5) The suppressive effect of incoming fire is considered for both movement and outgoing fire.

The combat model has the following detailed features:

- 1) It considers the events and conditions just prior to entering combat as well as the combat itself. Thus allowing study of the effect of pre-combat conditions and of entry into and exit from combat.
- 2) It considers ambush, attack, defense and meeting engagements.
- 3) It is stochastic and considers the attributes of each man on both sides. It considers individual fire-target combinations.

- 4) It relates the progress and the outcome of combat operations to environmental variables such as terrain, weather, etc., as well as to the combat power on each side.
- 5) It allows a study of combat alone or combat in combination with reconnaissance and/or in combination with the complete SIAF mission.
- 6) It considers EFS and organic weapon combat.
- 7) It allows user-input to many of the variables and decision factors so as to study the effect of variations of these.

#### SUMMARY OF ACTIVITY

##### Technical Objective

The objective of Contract DAAH01-73-C-0914 "Modification to Math Model for Small Independent Action Forces", is to improve the capability and utility of the previously developed SIAF model.

##### Technical Requirements

This section discusses each of the requirements specified in Technical Requirement Number 1816, which is an attachment to the contract.

1.0 Digital Elevation Data - The SIAF model now has the capability to use digital elevation data from tapes provided by the Defense Mapping Agency. Using subroutines created by the Systems Analyses Group of USACDC, a TOPOCOM tape is unpacked and a disk file is created for the area of operations. This disk file contains elevation data at the maximum resolution. When the SIAF model is run, the elevation data is read from the disk at the desired resolution. Changes were made to the storage sequence for elevation data such that the area of operations can be of any dimensions. The USACDC supplied subroutines are described in Volume III, Sections 10.5 to 10.7 (MAPGEN, CONVERT, ROTATE).

1.1 Tape Supplied - The SIAF sample case was run using a TOPOCOM tape containing elevations from the northern half of map sheet 1755I. This area is part of the Hunter-Liggett Military Reservation near King City, California. The maximum resolution of the data is 12.7 meters.

1.2 Variable Terrain Resolution - The capability is provided for varying the terrain resolution when changing from a reconnaissance mode to a combat mode and vice versa. At the start of the model the elevation data is read from the disk according to reconnaissance resolution by Subroutine RCREAD (See Volume III, Section 10.9). When a combat decision is made, the reconnaissance data is saved on a temporary file while Subroutine CMREAD obtains from the original disk file the elevation data at combat resolution (See Volume III, Section 10.8). Due to the requirement for more storage at greater resolution, the area considered during combat is smaller than the entire area of operations. The center of the combat area is determined dynamically by considering the SIAF position, target position, projected deployment point, and projected engagement point. The best shaped rectangle for containing these points is selected. In case the boundary of this area is crossed during combat the combat area is shifted. This is done by Subroutine OUTSID (See Volume III, Section 10.10). When the simulation returns to a reconnaissance mode, the old elevation data is retrieved by Subroutine CONMIS (See Volume VI, Section 3.14)

2.0 Vegetation, Microrelief, and Soil Shapes - The Terrain Submodel has been reprogrammed to consider vegetation, microrelief, and surface features as polygons. These polygons are input as rectangles, circles, or triangles. Dominant classes are used to describe the area not covered by a polygon. (See Volume II, Section 2.1)

3.0 Antipersonnel Mines - Capability has been added to allow a pre-planned Claymore mine ambush. In the reconnaissance mode the SIAF moves to the mine deployment area and hand emplaces the mines. When a target comes within detection range, control is shifted to the Combat Submodel to consider detailed detection, movement, and lethality of the mines. (See Subroutine MINES in Volume VI, Section 3.18).

4.0 Dynamic Action/Reaction - Provisions have been made to allow dynamic actions and reactions of the two opposing forces in combat. The action is taken following detection of the adversary. When the target detects the attacker, it can either

- withdraw
- deploy in place
- open fire
- ignore the detection
- rotate the formation
- move to best deployment position

The desired option is a user input. If the attacker detects a change in the original status of the target, it can withdraw, change its deployment point, or exchange roles between the maneuver unit and the base of fire. The target then gets to react one more time to a subsequent detection of a change in the attacker's intent. This capability is described in Subroutines REACT and CREAT (See Volume VI, Sections 3.16 and 3.17).

5.0 Internal Communications - An internal communications submodel has been added to the SIAF Combat Model to introduce delay times for communications between maneuver units. Three messages were incorporated for use requiring internal communications. These are "break contact" "change deployment point", and "exchange roles between the base of fire and the moving maneuver unit". For each message an heirarchy of preferred communications means is input. These are selected from visual hand signals, aural communication, radio, smoke grenades, and sending a messenger. Additional messages could be easily added to this list. Internal communications are controlled by Subroutine IC (See Volume III, Section 8.2).

6.0 Hand Grenades - Hand grenades have been added as an alternative weapon for a firefight. Logic was developed such that hand grenades are used at short ranges when the firer is highly suppressed. Existing routines in the Fire Control and Lethality Submodel were expanded to cover the employment decision and the simulation of the lethality of hand grenades. (See Volume VI, Section 2)

7.0 External Fire Support - An extensive effort was undertaken to provide a stochastic, dynamic model of external fire support during combat. Subroutines EFSTIM (See Volume III, Section 5.3) computes the times of arrival of either artillery shells or bombs. This is based on the tactical situation and the input delay times associated with requesting fire

support. Subroutine EFS1 (See Volume III, Section 5.2) stochastically computes the effects of each burst. This is based on input range and deflection errors, ballistic dispersion errors, and lethality data. Provisions are included to adjust firing between volleys when an observer is present.

8.0 Model Demonstration and Validation - This requirement calls for the performance of test runs on the USACDC 6500 computer at Fort Leavenworth, Kansas. These test runs are to be selected from historical examples, field tests, or other appropriate sources. They are to be used to verify the predictive capabilities of the integrated reconnaissance and combat SIAF model. Considerable effort was undertaken to discover appropriate data sources to use for a test case. The SIAF model requires very specific inputs in terms of a detailed operations plan, a tape containing the elevation and vegetation data for the area of operations, the weather, and detailed information on the locations of the targets. In the Combat Model, the SIAF makes decisions based on input decision criteria. Although extensive data was collected by The Vertex Group of the Research Management Corporation on historical SIAF operations, the data requirements for a simulation were not met. In the area of field tests, it was found that the only appropriate field test was the reconnaissance test performed at Hunter-Liggett in 1971. This was previously simulated and the results are presented in Volume I, Section 6. It does not include any of the combat model.

The approach taken by TRW to satisfy this task was in two parts. The first is a detailed validation through an experimental field test of the line-of-sight prediction portion of the model. This was felt important because it is a key driver of the events in the model. For this purpose an experiment was performed at the Hunter-Liggett Military Reservation where line of sight distances were measured from known locations at various headings. This test was simulated using the appropriate portions of the SIAF model with the elevation data tape from the Defense Mapping Agency. Resolution was varied from 12.7, 25.4 and 50.8 meters between elevation points. Results were found to be very close for rolling terrain at the 12.7 meter resolution, with a fast decline in accuracy as resolu-

tion was lowered. The simulation was also performed using the ASARS technique of modelling relief. It was found that the SIAF technique was slightly more accurate at 12.7 meter resolution and that the ASARS technique did not give credible results at lesser resolutions. This test is described in Volume I, Section 8.

The second step in model verification is to present a detailed examination of a sample case. This case is to be demonstrated at the SIAF Executive Overview Meeting on 18 January 1974 at Fort Benning, Georgia. The presentation will show the decisions, events, actions, and results of the SIAF simulation for a typical scenario. A qualitative assessment is to be made by experienced SIAF personnel. The sample case is also presented in Volume I, Section 6.

9.0 Documentation - The documentation for the current contract is provided as augmentation to the documentation from previous contracts. The most recent version was published in December 1972. All routines that were added or modified are to be replaced or added as specified in the augmentation instructions. The result is an integrated whole.

10.0 Train Government Personnel - A training class is scheduled for the week of 14 January 1974 at Fort Benning, Georgia. This class will teach analysts and programmers to understand, use, and modify the SIAF model. The class sessions are to be videotaped and placed in the videotape library at the U.S. Army Infantry School.

11.0 Stop/Restart - Capability has been added to the model to allow several stop points. At the point in the model that the stop point is reached, all of the common blocks are copied onto a disk. The model can then be restarted from that point for later use. This allows playing the combat portion separately and running it many times without repeating the earlier portions of the mission. This is performed by Subroutine RESTRT (See Volume III, Section 10.4).

12.0 Integrated, Debugged Model - The additions to the SIAF Model have been fully integrated with the previous version. The model has been debugged and is operational. At the time of this writing, it is scheduled to be installed on the CDC 6500 computer at Fort Leavenworth, Kansas

within a few days. Since the previous version is currently installed, no difficulties are foreseen.

13.0 Model and Documentation Requirements - Standards for the model and the documentation have been fully followed from USACDC supplement 1 to AR-18-7 Appendix M.

This document, prepared under ARPA Contract DAAH01-73-C-0914, contains changes and additions to Volume I, of the SIAF System Model User's Manual, 15 December 1972; hence, these pages replace or augment appropriate pages of the above referenced document. Table I provides instructions for accomplishing these changes to Volume I. (The pages in this document appear in the order in which they are referenced in Table I. As shown in Table I, for example, Pages i through ix of this document replace Pages i through xiii of Volume I of the User's Manual dated 15 December 1972.

## 1.0 INTRODUCTION

The Small Independent Action Forces (SIAF) System Model User's Manual consists of six volumes. Volume I provides the information necessary to actually operate the model on the computer while Volumes II, III, V and VI provide the more detailed analysis and discussion of the subroutines.

Volumes II and III contain the reconnaissance routines developed under ARPA Contract DAAH01-71-C-0100 while Volumes V and VI are the combat routines developed under Contract DAAH01-72-C-0305. All of the volumes have been modified under Contract DAAH01-73-C-0914.

These volumes are as follows:

- Volume I - Model Description and Programming Guide
- Volume II - Reconnaissance Subroutines (Terrain, Weather, Targets)
- Volume III - Reconnaissance Subroutines (SIAF Functions and Ancillary Routines)
- Volume IV - Model Program Listing
- Volume V - Combat Initialization Subroutines
- Volume VI - Combat Execution Subroutines

The first volume contains general information concerning the use of the model. The first section contains a qualitative description of the model and associated subroutines. This is followed by sections which present alphabetical lists of the model input and output variables. Next, the model subroutines are presented and summarized (details of each subroutine are contained in Volumes II, III, V and VI). Finally, a sample case consisting in part of the simulation of a test conducted at Hunter Liggett Military Reservation and computer operating procedures are included.

## 2.0 PROGRAM DESCRIPTION

The SIAF system model is a computer simulation intended for use in evaluating the effectiveness of alternative SIAF concepts. This model essentially accepts as input a military operations plan, such as would be prepared by the military commander for an actual patrol operation, and simulates this operation in a computer environment. It considers a small independent action force which follows this operations plan, and considers both reconnaissance and combat missions. The SIAF model simulates the interaction of the operations plan with the terrain, weather, and enemy situation and considers a total mission from beginning to end. The output of the model is the effectiveness of the particular operation under consideration. During the simulation of the activities and events which occur during SIAF operations, the model calculates statistics pertaining to movement, navigation, surveillance and detection, fire support, supply maintenance, human maintenance, and communications. The specific objectives of this modeling effort were as follows:

- 1) Develop a methodology for modeling a SIAF patrol and implement the methodology.
- 2) Quantitatively measure the reconnaissance and combat effectiveness of alternative SIAF concepts.
- 3) Identify those variables which have the greatest impact on the overall effectiveness of SIAF.

### 2.1 SIAF MEASURES OF EFFECTIVENESS

In order to satisfy the objectives stated above, one of the first tasks that had to be performed was that of defining appropriate measures of effectiveness for SIAF since these are essentially the outputs of the model. For this purpose, experienced patrol leaders representing various military organizations were interviewed. Based upon these discussions, a list of measures of effectiveness was identified. Some of these measures are shown in Figure 2.1.

As an example of how these measures are applied to a SIAF problem, consider a situation where the user desires to compare the relative merits of two sensor systems, one of which is bulkier and requires a larger crew but is very reliable, versus less reliable equipment which is lighter and

| ● NUMBER OF TIMES SIAF IS DETECTED | <u>COMMUNICATION MOE'S</u>                       |
|                                    | ● COMMUNICATION SUCCESSES/COMMUNICATION ATTEMPTS |

Figure 2.1, Typical SIAF Measures of Effectiveness

requires a smaller crew. For this purpose, measures such as detection per detection opportunity and man days per detection might be selected as being fundamental. Given such data, trade-offs are readily obtained providing useful guidance for research and development decision making. For examining and answering questions pertaining to engagement, the classical measures: casualties, exchange ratio (enemy casualties/SIAF casualties), and survivor ratio (SIAF survivors/enemy survivors) are computed. These measures are often used in the evaluation of competing patrol weapons mixes. Another possibility is that one might not be interested in casualties, per se, but in the number of times SIAF is able to direct fire on the enemy. This measure is also calculated by the model.

Ancillary statistics are intended to be of value for elucidation of cause and effect relationships. As a simple example in the use of these statistics, suppose that it is consistently found that battery life is a principal cause of communication failures. Given typical patrol durations and communication frequencies, a clear justification is available for a development effort aimed at extending power source endurance.

In summary, because of the requirement for the model to apply to general SIAF problems, a large number of measures and ancillary statistics are calculated and provided by the model. Application of the model requires that the user select from these data those statistics which pertain to the particular problem of interest. (Details of the model outputs are provided in Section 4.0 of this volume.)

## 2.2 MODEL APPROACH AND REQUIREMENTS

The approaches considered for the SIAF model included an analytical model, war gaming, and computer simulation. During this evaluation, a purely analytic model was discarded since it does not have the generality necessary to meet project requirements. War gaming is too slow and unwieldy for most SIAF purposes and is usually valuable only if copious resources and time are available. Field exercises and combat testing were also considered but were ruled out since, at times, conceptual systems must be studied by the decision maker. Simulation using analytical submodels was judged to combine the necessary generality and flexibility with acceptable speed and economy. The

computer simulation method allows for comparing alternative concepts (i. e., different mixes of personnel, material, and procedures) within a scenario of fixed conditions and assumptions. For the SIAF project, it constituted a clear first choice.

Once simulation was selected for developing the SIAF mathematical model, the next task was to prepare specifications for developing this model. The purpose of these specifications was to identify required model inputs, outputs, and submodels. To this end, it was recognized that the measures of effectiveness illustrated in Figure 2.1 depend upon five basic factors which are the terrain, weather, enemy situation, friendly situation in terms of units which support SIAF operations, and the specific SIAF operations plan being considered. Since the basic purpose of the model is to estimate the effectiveness of SIAF operations as a function of changes in these factors, they were essentially identified as inputs to the model. This is illustrated in Figure 2.2.

In identifying the submodel areas, a vigorous effort was made to develop a model which is as realistic as possible. To this end, it was recognized that in the real world a patrol leader prepares an operations plan before he starts the mission. In this operations plan, he considers the functions of movement, navigation, surveillance and detection, fire support, supply maintenance, human maintenance, communications, and command and control. In addition, these are the essential functions the patrol performs during the execution of the plan. Hence, these areas, in addition to terrain, weather, and enemy, were identified as the major areas for submodel development. (See Figure 2.3.)

Although submodels in each of these areas could conceivably be independently developed, a realistic simulation of patrol operation must also consider the interactions of the functions shown in Figure 2.3 with each other and the weather, terrain, and enemy situation. For example, the movement rate a patrol selects will be a function of the terrain and weather, pack weight, and fatigue of the patrol members. This will have an impact on the patrol duration, distance traveled, the visual detection capability of the patrol, and the possibility that the patrol is detected. That is, if the patrol moves rapidly over rough terrain, the patrol surveillance capability is decreased since more attention must be devoted to

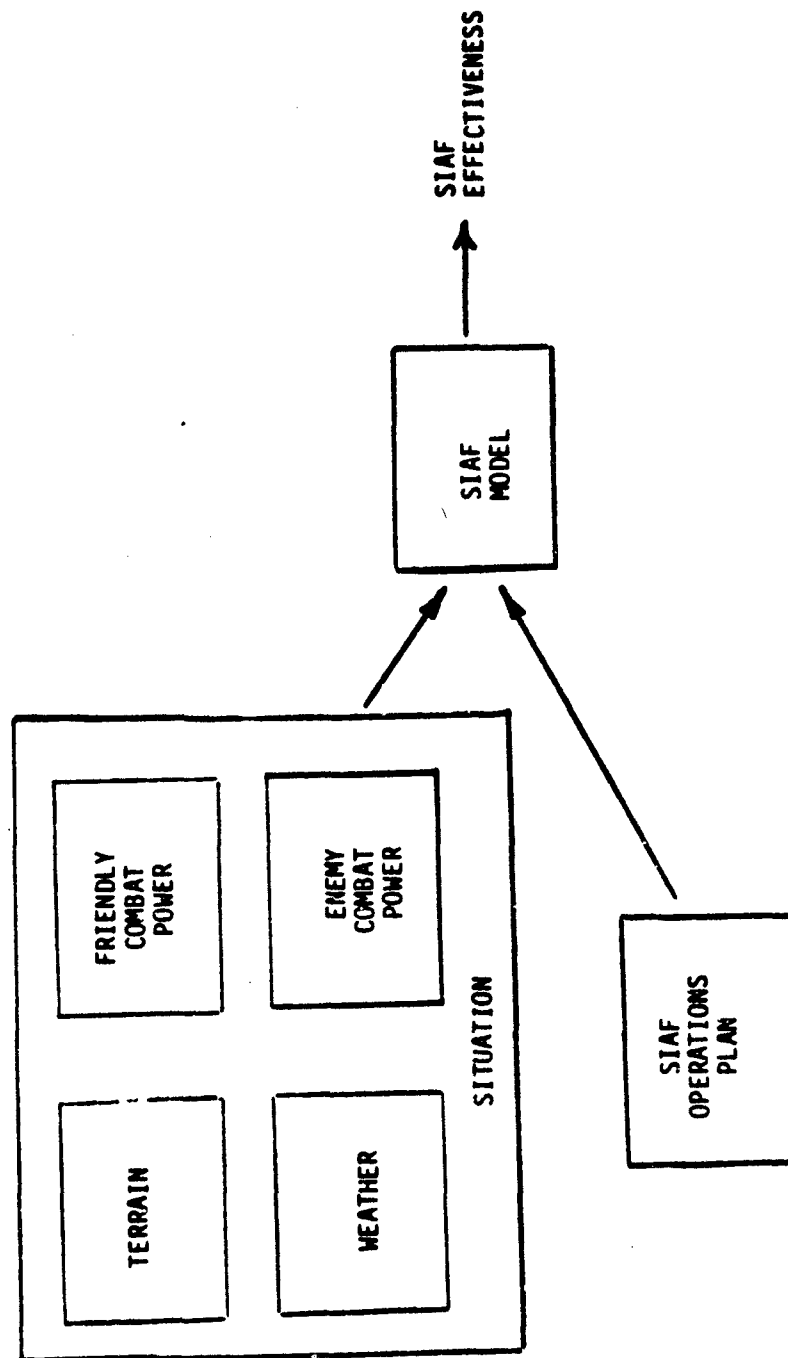

Figure 2.2, SIAF Model Overview

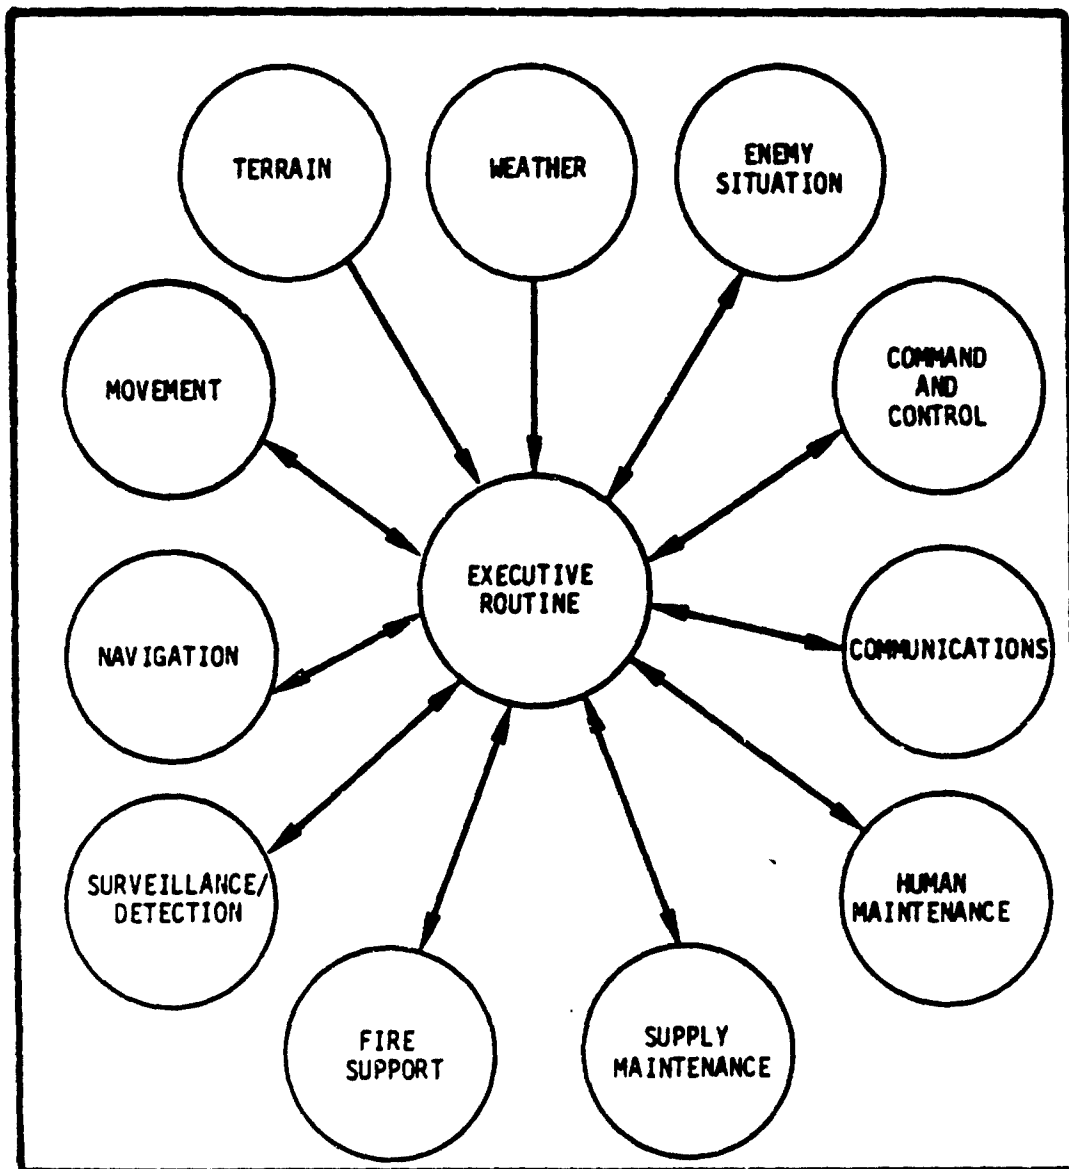

Figure 2.3, SIAF Model Elements

movement and, consequently, less can be devoted to surveillance. In addition, movement is a cue for visual detection and, hence, increases the possibility of detection by the enemy. This patrol movement rate also influences the energy expenditure rate of the patrol and the food and water requirements which are functions of the temperature and humidity and which, in turn, influence subsequent patrol movement rates. These are examples of the complex interactions which are considered in this model. These interactions are extremely important since equipments and tactics which lead to improvements in some areas could possibly result in a decrease in effectiveness in other areas (see Figure 2.1).

### 2.3 THE EXECUTIVE ROUTINE

The performance of many of the functions identified previously depend upon physical environment parameters of terrain and weather; as such, these subroutines use this information as input data. The problem here is that the physical environment parameters change with the location of the patrol on a route such as that shown in Figure 2.4; however, the subroutines are constrained to accept only a single value for a particular variable. A simple solution to the problem is to time step the patrol through the route using small time intervals. The idea, of course, is that if the time intervals are sufficiently small, one can assume that the appropriate physical environment parameters are constant during this interval. This approach, however, was not selected since it was felt that this would result in excessive model running time. A time step of 30 seconds, for example, would result in 28,800 time intervals for a patrol with a 10-day mission. Also, visual detection probability changes drastically as a function of light level; hence, it is desirable to examine events on a shorter time interval basis during periods of sunrise and sunset.

The possibility of using a purely distance driven simulation was also considered. However, this approach is complicated by the fact that the patrol may conduct stationary reconnaissance operations for long periods of time and normally reports its position and status to the base on a periodic basis (a function of time). Also, some targets are of such a nature that they may enter and leave the simulation as a function of time,

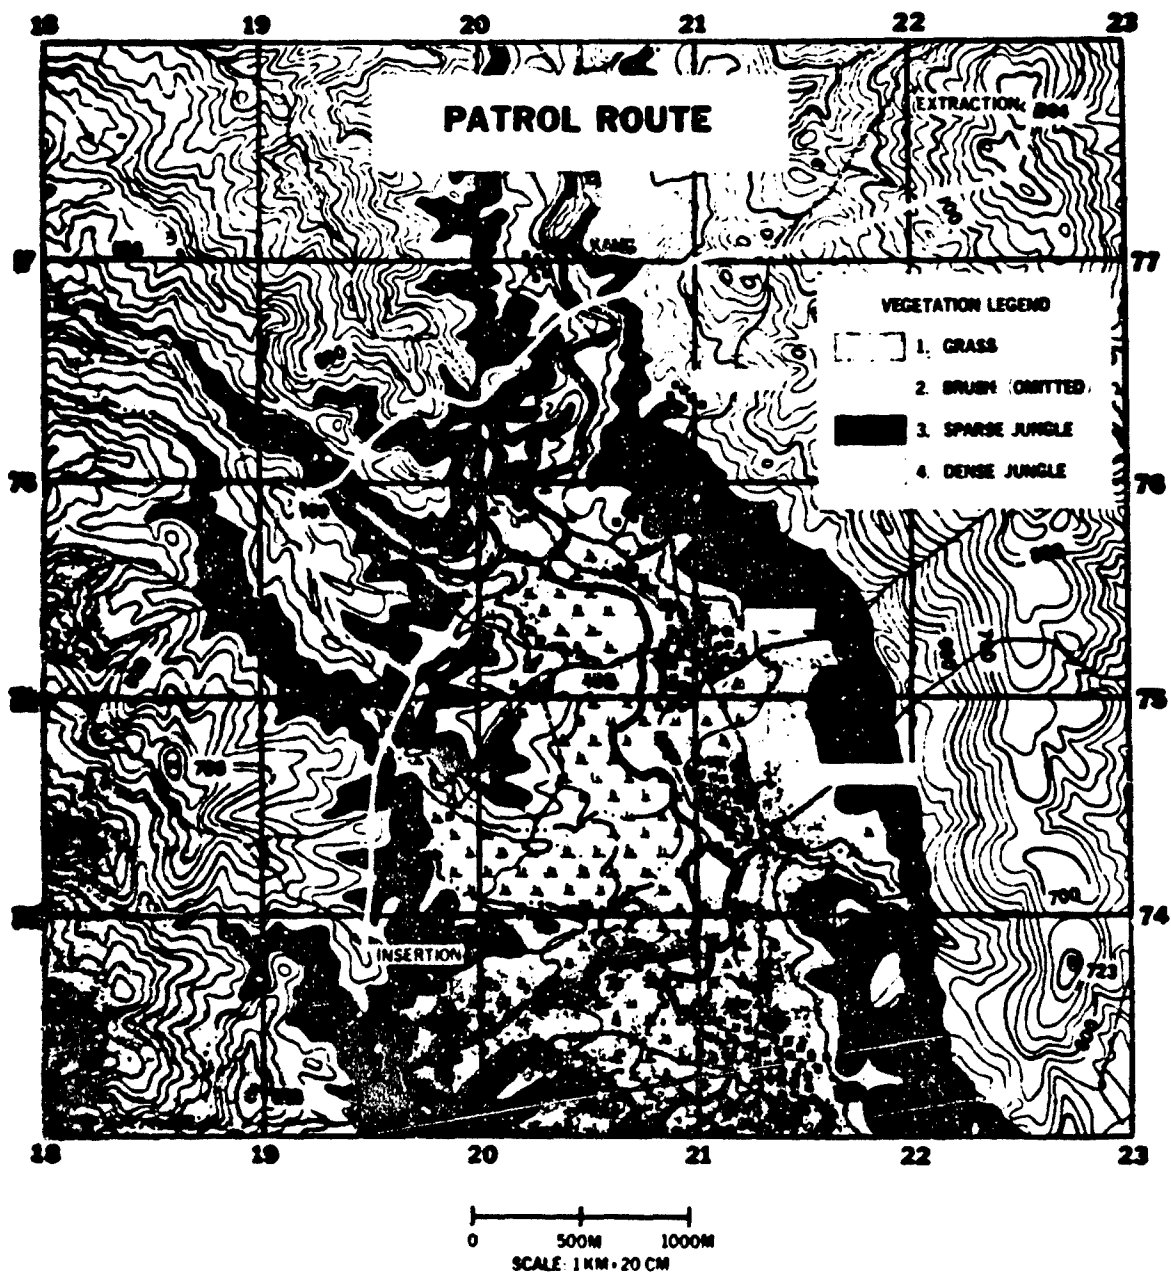

Figure 2.4, Patrol Route

Revised December 1973

further complicating the manner in which the model is driven. Likewise, a purely event driven simulation was discarded since events such as movement and surveillance and detection are continuously occurring in patrol operations.

The resulting executive routine essentially consists of a marriage of these ideas. The basis of the concept is a grid square approach for inputting digitized terrain data and is illustrated in Figure 2.5. With this approach, a map of the area of operations is divided into grid squares whose resolution is user input. The total area is assigned a vegetation class with exceptions to this as subareas (polygons), in the form of rectangles, circles, and triangles (user input) assigned to the total (see Volume II for discussion of the terrain model). Based upon the axis of advance of the patrol, a segment, defined as the distance of the first grid crossing, checkpoint, obstacle, or polygon crossing, whichever is smaller, is first generated as shown in Figure 2.5(b). The movement rate over this segment is next calculated and a segment time is computed. This segment time is then checked to see if any target movement or communication events are to occur within the segment. If so, the segment is redefined as the distance the patrol moves to the time that particular event is scheduled to occur. Once a segment is defined, statistics pertaining to the functions shown in Figure 2.3 are calculated and accumulated for the segment. After these calculations, another segment is generated and the process is continued until the last checkpoint is reached.

If the SIAF patrol is stationary, a time driver subroutine drives the model and uses criteria of light level and target movement for determining the time step. During periods where the light level is relatively constant and targets are beyond feasible detection ranges, the time interval selected is large. When light level changes rapidly the time step is automatically reduced to account for the change in visual detection capability which occurs in this situation. Again, statistics pertaining to the functions shown in Figure 2.3 are accumulated for each time segment.

In addition to the distance and time segments defined previously, a subset of these called mini-segments are also generated when detections are feasible. Figure 2.6 illustrates this concept which operates as follows: During a simulation of the mission, many of the targets in the area of operations are not feasible of being detected because of the distance between them and the SIAF patrol. For each segment, feasibility of

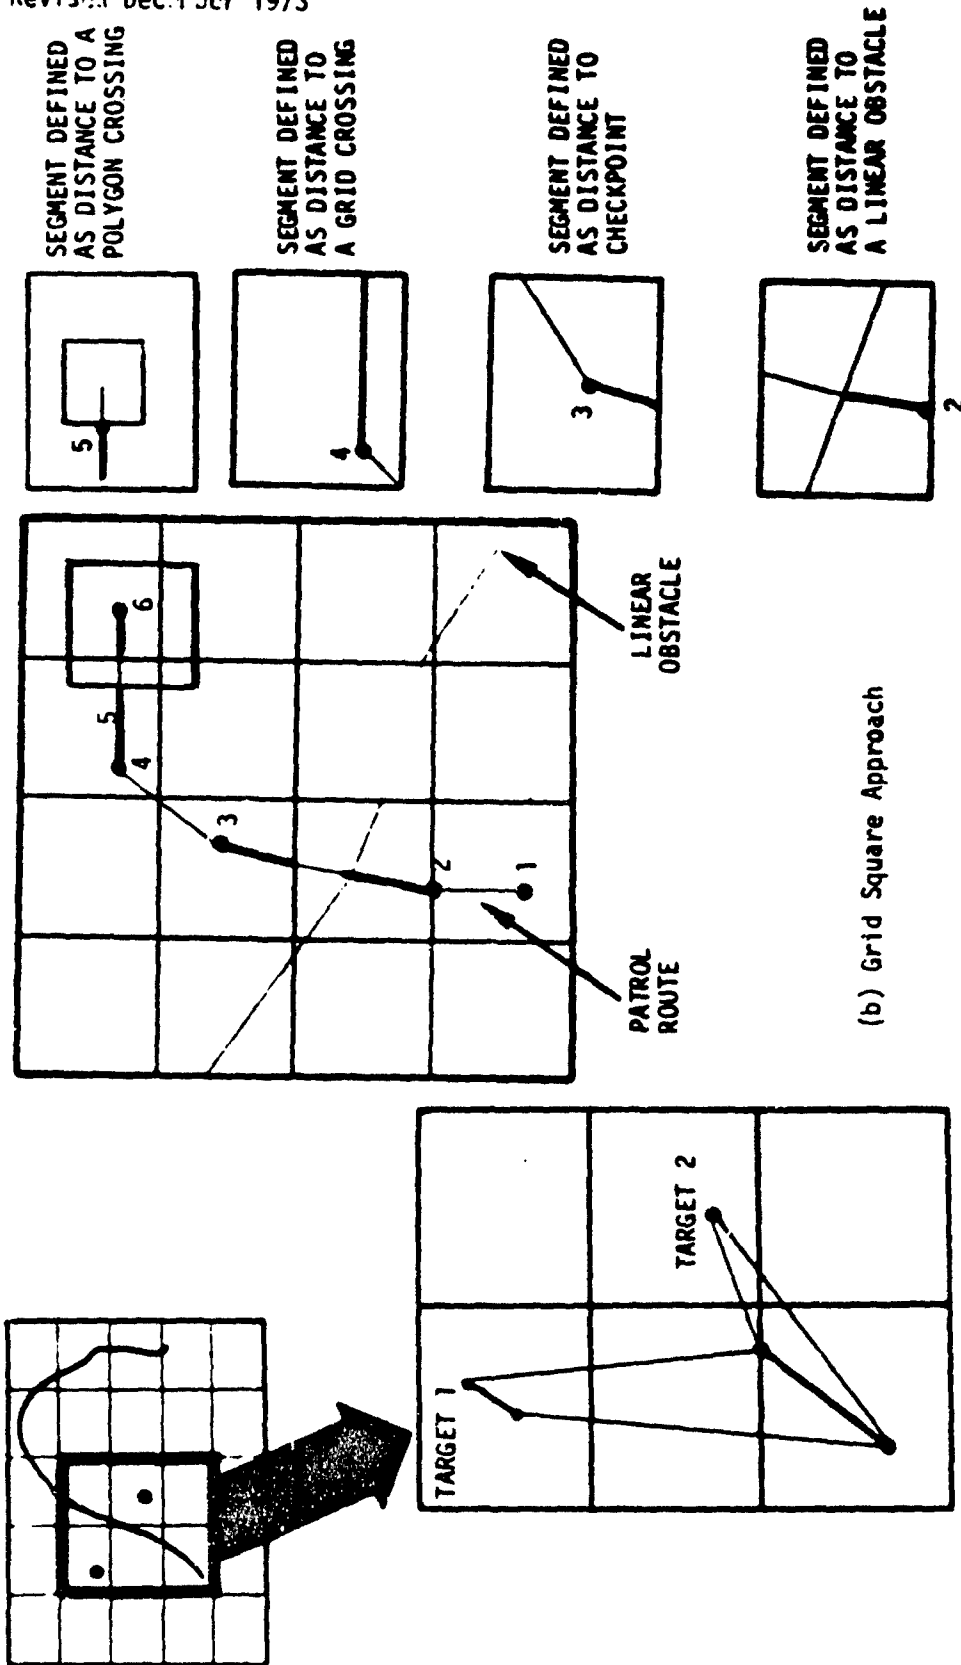

Figure 2.5, Generation of a Distance Segment

(a) Area of Operations

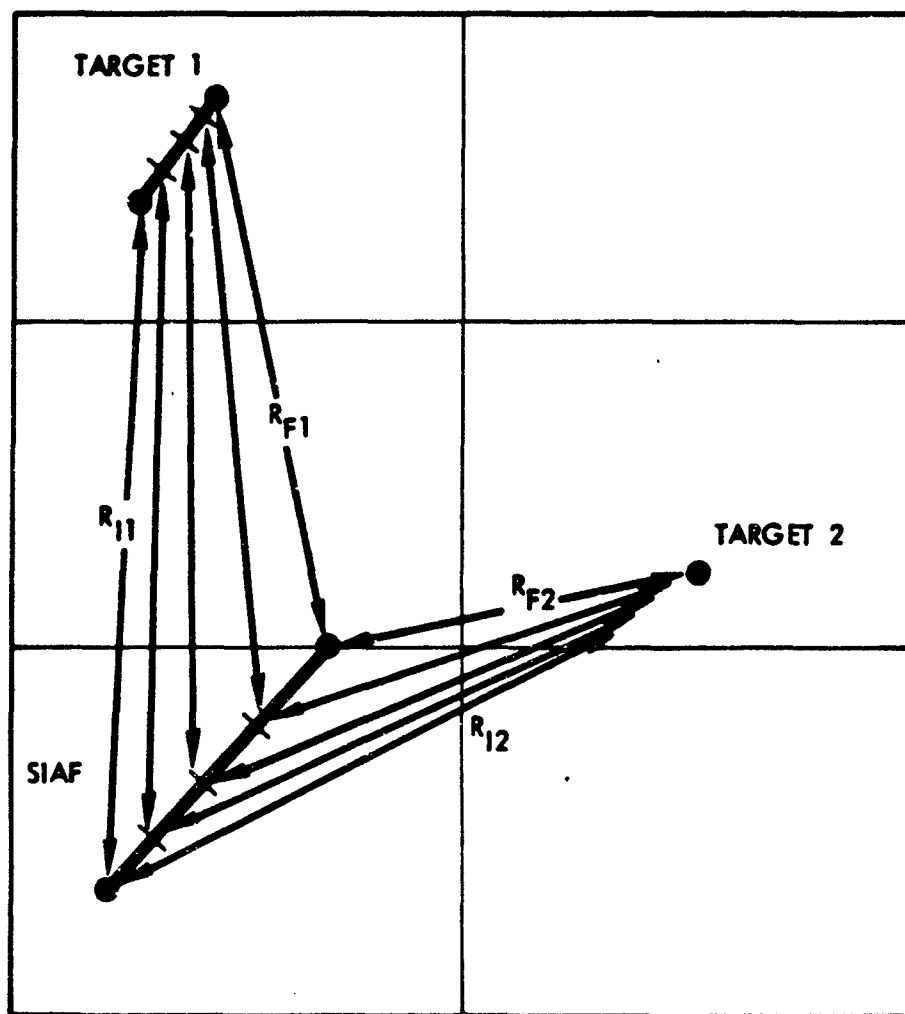

Figure 2.6, Illustration of Mini-Segments

target detection is checked at the minimum range point and, if not feasible, the target is not considered during the next series of calculations. If feasible, on the other hand, the line of sight between SIAF and the target could change as a function of their relative positions in the segments. In this situation, both SIAF and target segments are divided into mini-segments. The length of the mini-segments are user input. In this situation, the program advances SIAF and each feasible target, a mini-segment at a time, and determines a detection verdict for each mini-segment. For this calculation two options are available: In the first of these, the centroid of the patrol and each target are examined to determine if line of sight exists. If so, then it is assumed that line of sight exists between all members of each group. The user also has the option of treating man-to-man intervisibility in which he can consider the relative location of each individual in both the patrol and target formations (see the Surveillance/Detection Submodel, Volume III, Section 4.0, for the details). This option accounts for the fact that some of the individuals in a particular group may not be visible by all members of the other group. Thus, the user can consider the patrol as one point or consider individuals as desired. These options essentially serve to automatically increase the resolution of the model when required and use less detail resolution when this is appropriate. All of these features serve to minimize the running time of the model and provide the user the option of selecting the resolution he desires.

## 2.4 SIAF SUBMODELS AND SUBROUTINES

In this section, each of the submodels shown in Figure 2.3 is summarized and the interactions among them are described. The subroutines described herein are listed in Section 5.0 of this volume for ease in referencing. Volumes II, III, V and VI contain detailed information concerning these submodels and subroutines.

### 2.4.1 SIAF Terrain Submodel

The purpose of the SIAF Terrain Submodel is to provide a representation of the terrain for use in line-of-sight and slope calculations,

and for considering factors such as the vegetation at various points in the area of operations as required by the other subroutines. This submodel considers the following factors:

- Relief
- Vegetation
- Obstacles and Cultural Features
- Micro-Relief
- Surface Materials

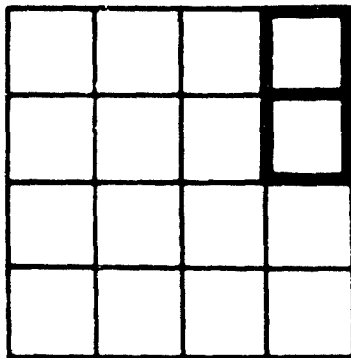

The manner in which these factors are treated in this submodel is summarized below.

#### Relief

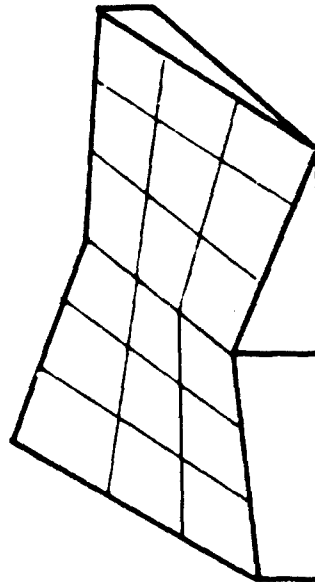

The basic approach for treating relief is to divide the map into grids, whose size is a user input. The grid elevation data is obtained from a military "TOPOCOM" tape of the area of operations. The tape contains digitized elevation data of various areas and is of a high resolution. Thus, the elevation data represents the elevation at each corner of the grid square. Based upon these data, the model generates a hyperbolic surface between the points for each grid square. Figure 2.7 illustrates this surface for two grid squares. In order to explain and illustrate the results which are obtained with this approach, an ionic model of four grid squares was developed. Figure 2.8 is a photograph of this model. It illustrates the curved surface which is obtained from the four-corner input data.

As an example of the impact of various resolutions on the accuracy of the relief representation, a study was made using Army map sheet 1755 IV NE, Alder Peak California, 1:25,000. Figure 2.9 shows actual contours and the contours which result from this model using 100-meter resolution. These 100-meter data were obtained from a listing of an Army digitized terrain tape of the area. The Figure illustrates how much of the section of road can be observed from the observation post for both sets of contours; there is considerable error in the results obtained from the model when the 100-meter resolution is used. Figure 2.10 shows the same situation for 50-meter resolution. These illustrations show that accuracy

of relief representation is considerably better with 50-meter resolution. It is interesting to note that the terrain for which this comparison was made is fairly rugged. Hence, the preceding analysis probably represents a worst-case situation.

Further comparison of the relief part of this model to field experiments is presented in Section 8.0 of this model.

### Vegetation

The problem of appropriately modeling the vegetation factor of terrain for SIAF was approached in two steps. First, it was necessary to develop an appropriate vegetation classification scheme. Second, it was necessary to determine the manner in which this scheme could best be used, in conjunction with the relief portion of the Terrain Submodel.

The vegetation classes considered in this submodel are summarized in Figure 2.7. As shown in the figure, each class of vegetation consists of a certain amount of grass, brush, and trees. The features within each class are assumed to be distributed at random. To the total area for which elevation is input is assigned one number from 1 to 12 to represent the class (dominant) of vegetation to be found within the area. Exceptions to this are inputted as subareas in the form of triangles, circles, and rectangles and are also assigned a number from 1 to 12 and are used to represent subareas of vegetation other than the dominant within the total area.

In developing this classification scheme, an attempt was made to include consideration of the types of vegetation which might be found in various parts of the world. In addition, an attempt was also made to gather realistic data concerning the density and size of the vegetation features within each class. To this end, various references (indicated in Volume II) were studied. The data in these references were augmented by a field trip to Hunter Liggett Military Reservation where aerial photographs of the area were obtained and a ground survey was conducted.

Figure 2.12, Class 5 Vegetation: Light Forest with Brush

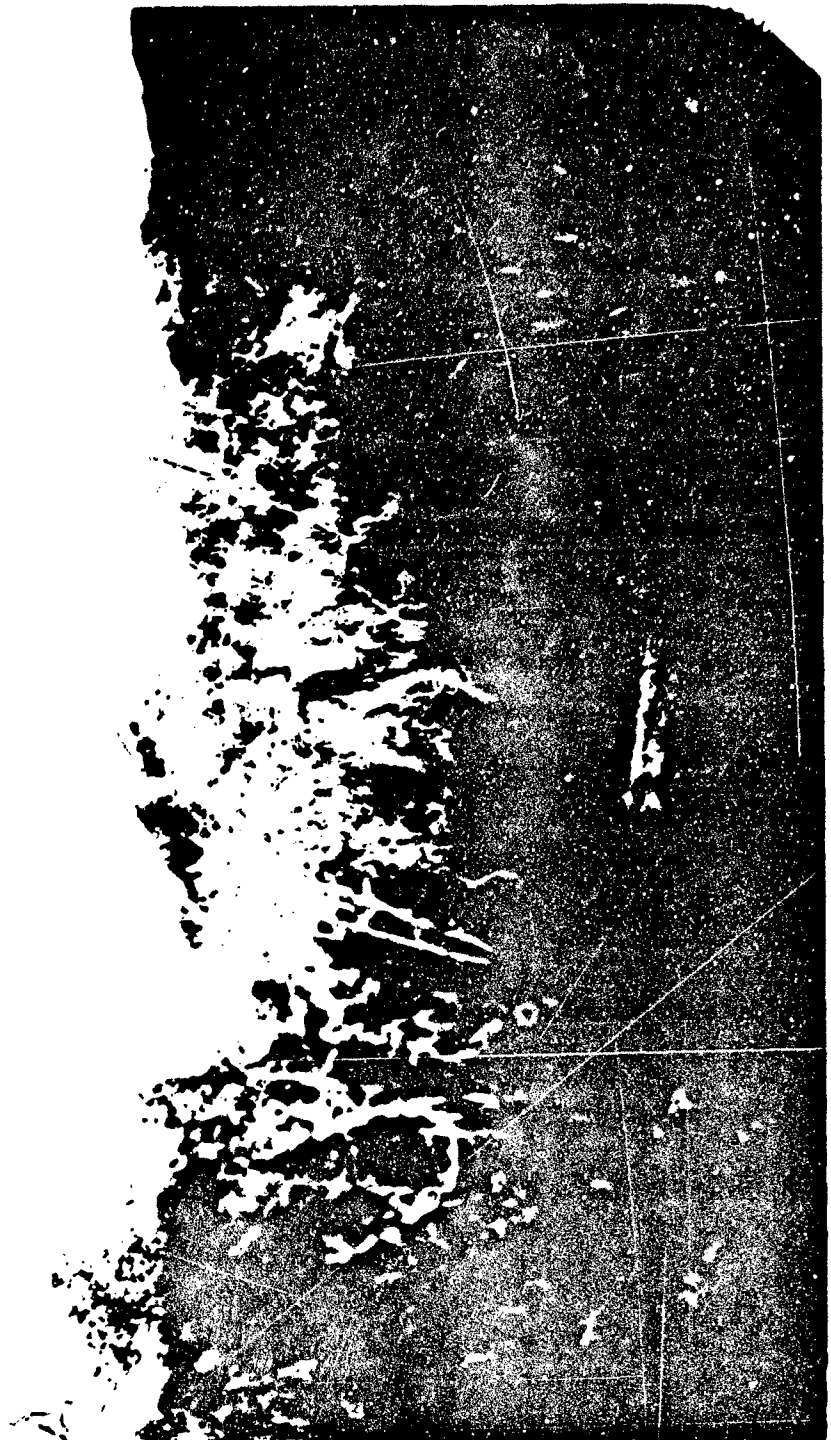

Figure 2.13, Class 3 Vegetation: Moderate Brush

Revised December 1973

Figure 2.11 presents one of these aerial photographs while Figure 2.12 provides a closeup view of the vegetation in the square of Figure 2.11. Figure 2.13 is a view of the vegetation in the area of the circle of Figure 2.11. The vegetation shown in the photograph of Figure 2.12 was subsequently defined as class 5, light forest with brush. Results of the ground survey indicated that there were approximately 63 features of brush per 50- by 50-meter square, each feature being approximately 2 meters wide and 3 meters high. In addition, the 42 trees in this area were judged to be an average of 10 meters high with 3-meter wide crowns. The vegetation shown in Figure 2.13 was found to be considerably different as might be expected from an inspection of Figure 2.11. This area was defined as class 3, moderate grass or brush, and was found to consist of 500 features of brush per 50-meter square. Each feature was judged to be a sphere with a diameter of approximately 1.5 meters.

As an example of the impact of the polygon (triangles, rectangles, and circles) overlay method of vegetation representation, Figure 2.14 shows the accuracy of realism that can be obtained through this method. As can be observed, considerable accuracy can be obtained.

#### Obstacles and Cultural Features

For the purposes of modeling, cultural features and obstacles are treated in the same manner as vegetation in that a polygon configuration resembling the feature or obstacle is overlaid on the area and is assigned a number which indicates the type of area obstacle. Cultural features such as roads, on the other hand, are input by means of straight line segments. Figure 2.15 summarizes obstacles and cultural features considered in this submodel and presents an example which illustrates the input procedure described above.

#### Surface Materials

The surface materials or soil classifications considered in this submodel are summarized in Figure 2.15. In preparing the inputs to the submodel, a dominant soil classification is assigned to the area of operations. Thus, if the area is considered to consist mainly of sand, then the number 2 would be associated with the area. Exceptions to this are input by a means of subareas in the form of circles, rectangles, and triangles illustrated in Figure 2.15. Thus, for example the shown, the cross-hatched area would consist of high plasticity silt (class 0) while the remainder of the area would have the dominant soil class (class 2).

# POLYGON BY EXCEPTION METHOD OF INPUTTING SOIL, MICRORELIEF AND VEGETATION

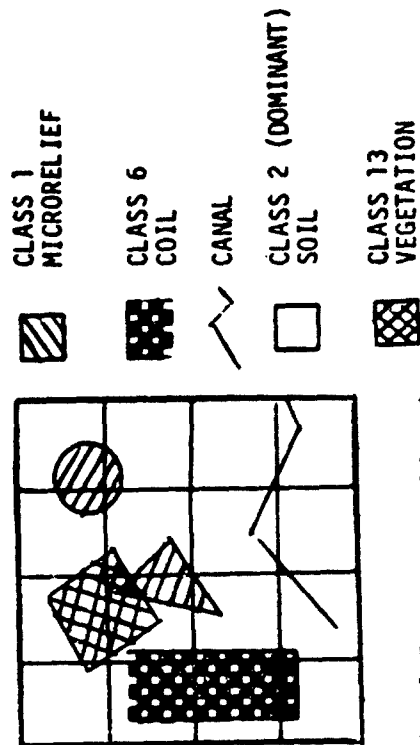

Figure 2.15. Terrain Model - Additional Factors Considered

### Micro-Relief

In addition to the factors considered in the foregoing discussion, certain terrain irregularities must now be considered. Figure 2.16 photographically illustrates some of these irregularities that exist at the Hunter Liggett Military Reservation. These irregularities are called micro-relief for this model. Here, positive undulations, negative undulations, and boulders are considered. Each class of micro-relief consists of a combination of these features of varying densities and sizes. These features are assumed to be distributed randomly within an area; they are input by means of circles, rectangles and triangles as illustrated in Figure 2.15. Thus, the cross-hatched region, as shown in Figure 2.15, would consist of that class of micro-relief desired by the user while the remainder of the area of operations would consist of a dominant micro-relief class.

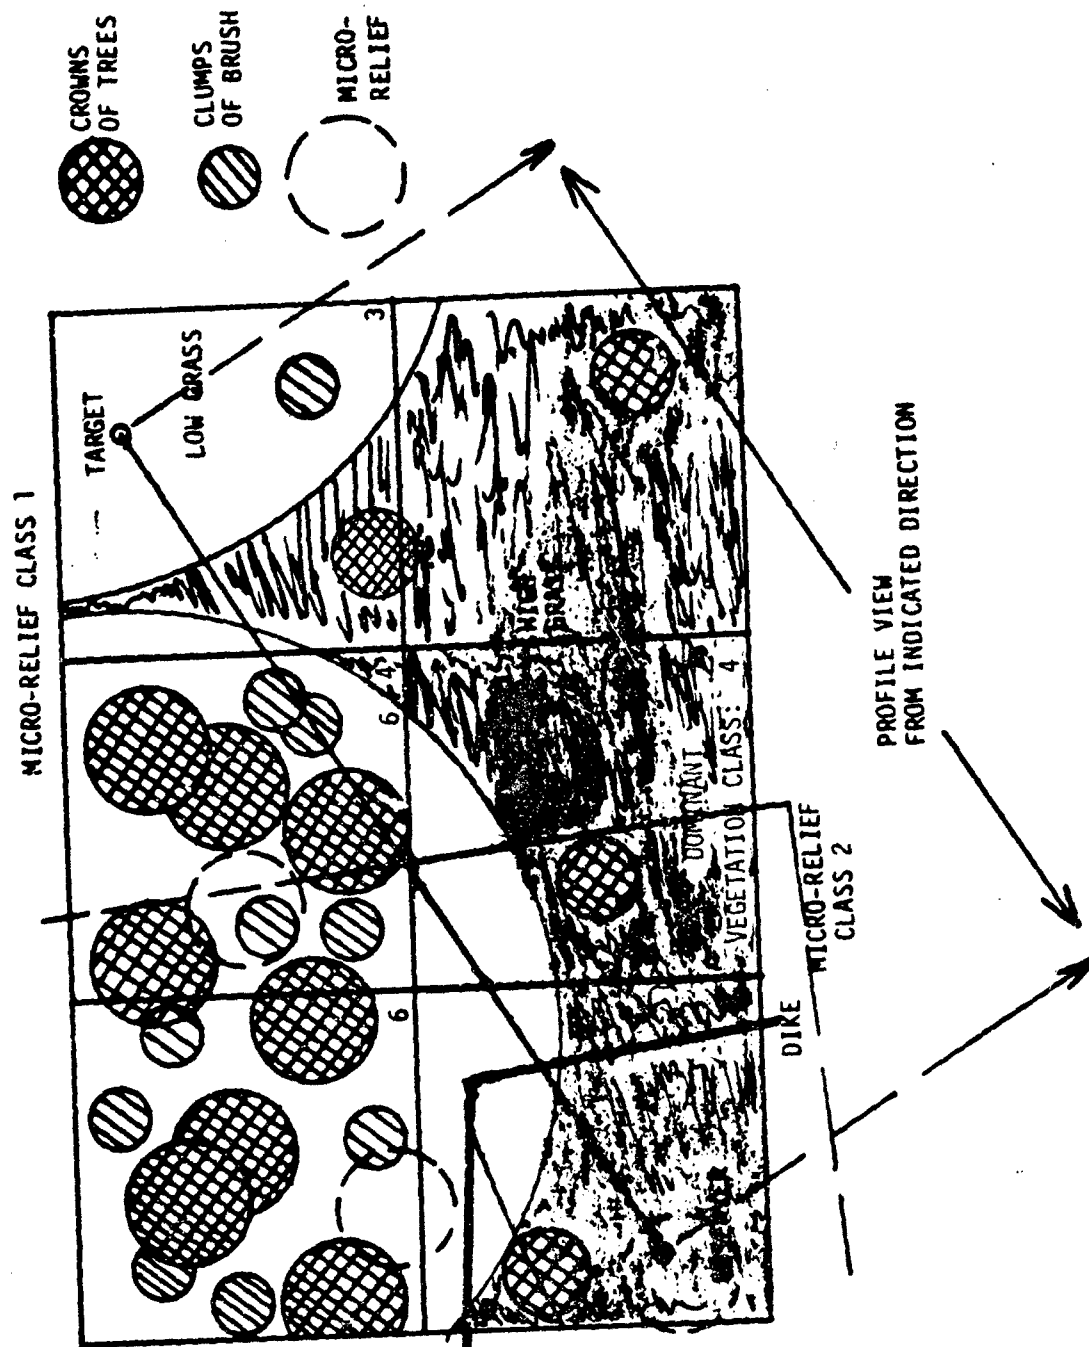

### Summary

To illustrate how these factors of terrain are combined in the model, Figure 2.17, which presents a top view of six grid squares, was developed. A profile view of this situation is shown in Figure 2.18. A study of Figure 2.17 and 2.18 indicates that line of sight could be obstructed for a variety of reasons. For example, line of sight could be obstructed by relief, an obstacle, features of brush, crowns of trees, or trunks of trees. The relief and obstacle line-of-sight decision is essentially a deterministic one which is based upon the geometry of the situation while the line-of-sight verdict due to vegetation and micro-relief is a probabilistic one. Furthermore, this probabilistic verdict depends upon the relative location of the vegetation features and the micro-relief features with respect to the observer and the target. For example, features close to the observer tend to have a greater impact on concealment probability than do those further away. See Sections 2.5, 2.10, and 2.11 in Volume II for concealment analysis and description of equations.

This total line-of-sight decision calculation is made by Subroutine TERCON which in turn calls eight other terrain subroutines as illustrated in Figure 2.19. Here, Subroutines MICSOL and MITFEA essentially determine if a target is on a micro-relief feature or on an obstacle such as a swamp. Both of these factors are used to adjust the height of the target

Figure 2.16, Micro-Relief Features

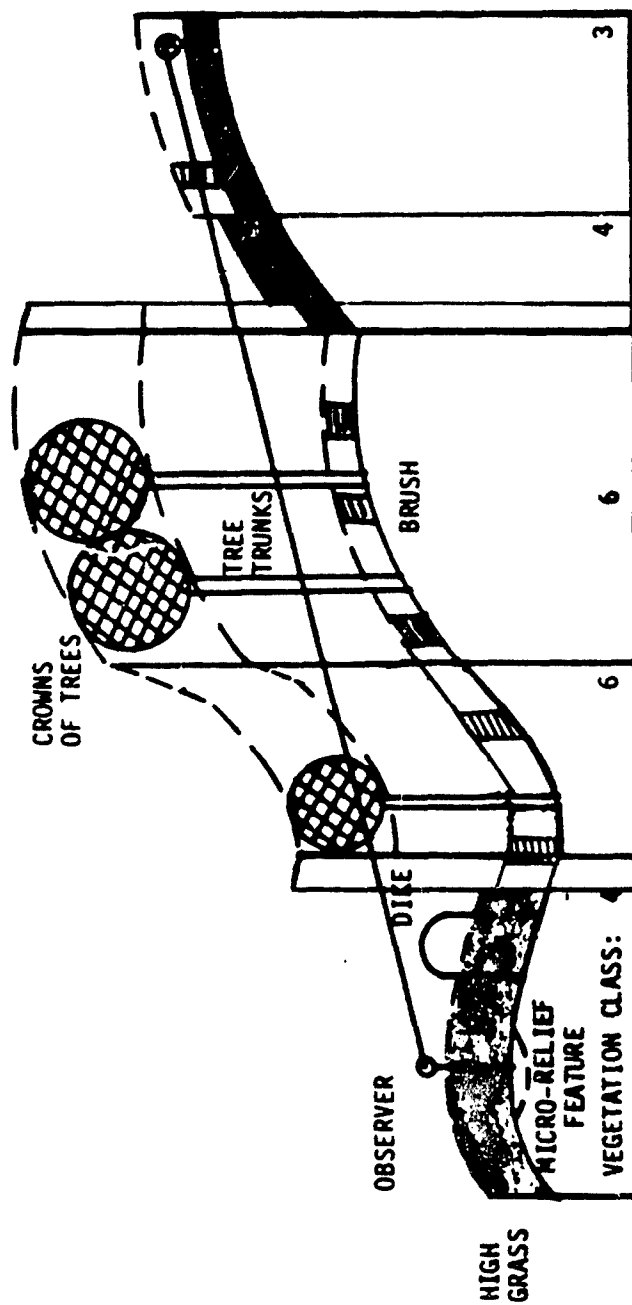

Figure 2.18, General Line-of-Sight Situation "Profile View"

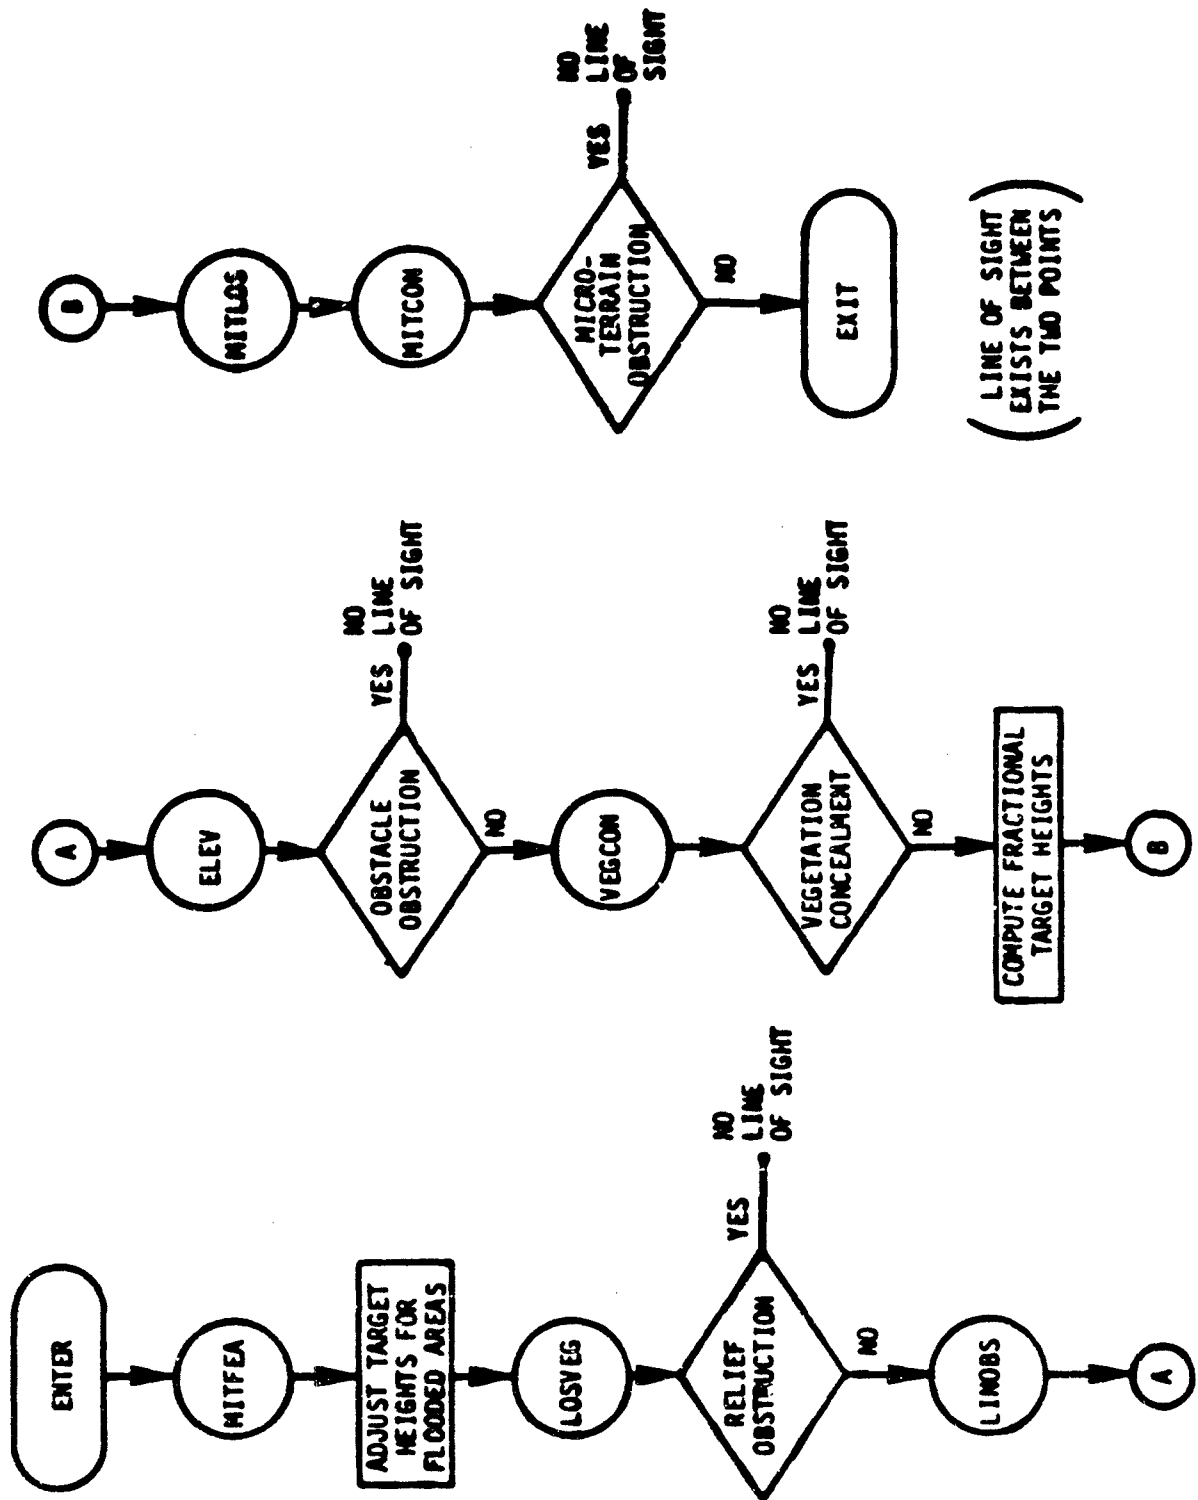

Figure 2.19, Terrain Concealment Subroutine (TERCON)

appropriately. Next, Subroutine LOSVEG is called and determines if there is a relief intercept between the two points of interest. If so, a no-line-of-sight verdict is returned by the subroutine. If there is not a relief obstruction, Subroutines LINOBS and ELEV are next called. These subroutines essentially determine if there is an obstacle between the two points of interest and determine the elevation of the obstacle. Based upon these calculations, a check is made for an obstacle obstruction and a line-of-sight/no-line-of-sight verdict is again made as shown in Figure 2.19. If line of sight exists, then Subroutine VEGCON is called to check the vegetation concealment. As part of this calculation it could turn out that a target is partially concealed because of vegetation. If so, the area of the target visible is calculated. The final two subroutines, called MITLOS and MITCON, determine if there is a micro-relief obstruction between the two points of interest.

In summary, Subroutine TERCON determines if there is line of sight between any two points in the area of operations. The line-of-sight verdict is based upon an examination of relief, obstacles and cultural features, vegetation, and micro-relief which exists between the two points under consideration.

#### 2.4.2 SIAF Weather Model

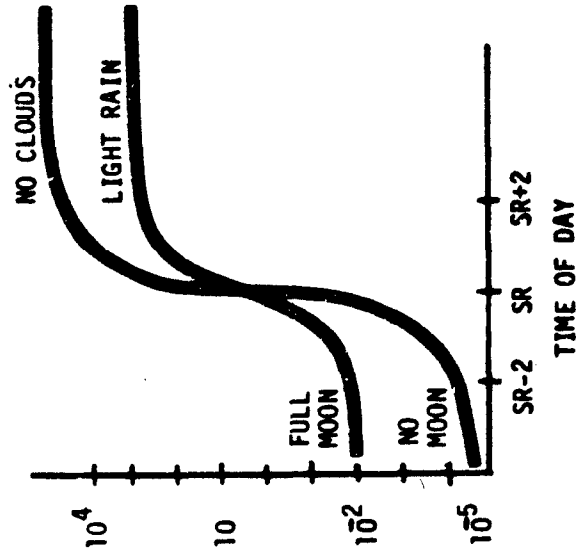

Figure 2.20 shows Weather Subroutine variables for weather classification, light level, temperature, and wind velocity. In the model, these variables are functions of time. When a subroutine needs a particular weather variable, the model simply examines the weather variables at the time in question and selects the appropriate values. The 11 classes of weather which vary from clear to heavy fog are input by the user as a function of time. Figure 2.21 is an example of the procedure to input variables for the Weather Subroutine.

The light level data of Figure 2.20 (foot lamberts versus time) were obtained from Reference 1 and, as shown, varies rapidly near sunrise (SR) and sunset (SS). (Only sunrise is illustrated in the Figure since sunset is essentially the reverse of this.) The model also considers the interaction of these basic light level data with the weather in that the light level is degraded appropriately depending upon the weather conditions which exist at the time the light level is sampled.

Figure 2.21, Example Weather Input Values

The temperature curve was derived empirically from data collected at Los Angeles Civic Center and Hunter Liggett Military Reservation. Examination of these data revealed that the temperature begins to increase approximately one hour after sunrise (SR) and reaches its maximum value about seven hours after sunrise. Then it stays relatively constant with time, starts decreasing approximately five hours before sunset (SS), and reaches its minimum value at three hours after sunset. Based upon these observations, the temperature model shown in Figure 2.20 was constructed. The maximum and minimum temperatures and the time scale for any locality for each day of the operation would be input by the user; then the model will generate a curve as shown in the Figure. Relative humidity (not shown) is treated in a similar manner, but it decreases as temperature increases.

Finally, the maximum, average, and minimum wind velocity is input by the user, and a random number is drawn to determine the appropriate velocity. Wind direction is input as constant. This sample procedure essentially accounts for gusts. If a constant wind scenario is desired, the user can simulate this by equating the minimum, average, and maximum velocities.

#### 2.4.3 Enemy Situation

Three options are provided in the model for treating the enemy. These are illustrated in Figure 2.22. As shown in the Figure, the user can have fixed enemy positions, can simulate an enemy movement in a random manner within a circular area of operations, or can simulate the enemy moving on a pre-planned path. For the random movement within a circle on the fixed targets, the user can either pre-select the initial positions of these targets or can have the computer select these positions at random. Targets such as trucks, personnel, and enemy caches are simulated by inputting appropriate target characteristics. Analyses and discussion of target movement are contained in Sections 4.1 and 4.3 of Volume II.

Subroutines pertaining to the SI&F functions are described next. These subroutines are exercised for each segment as discussed in Section 2.3.

#### 2.4.4 Movement

This subroutine calculates the movement rate of the patrol to be consistent with maintaining good surveillance and detection capability. Figure 2.23 presents a simplified flow diagram of how this movement rate,

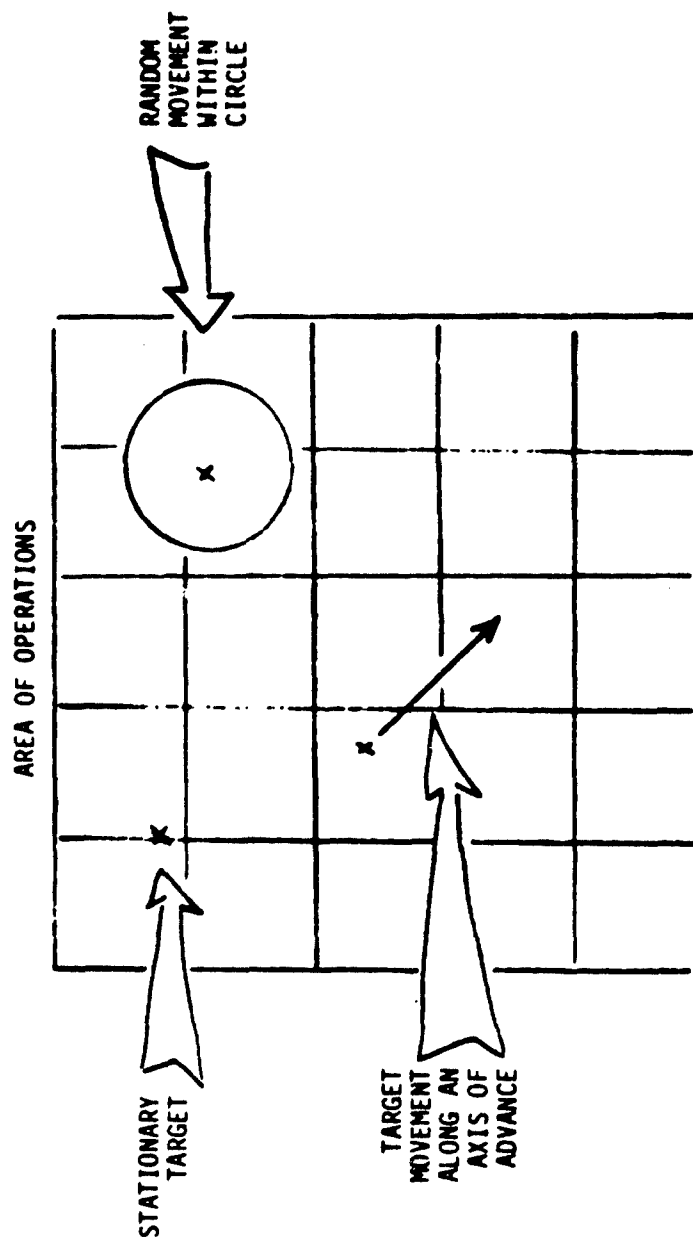

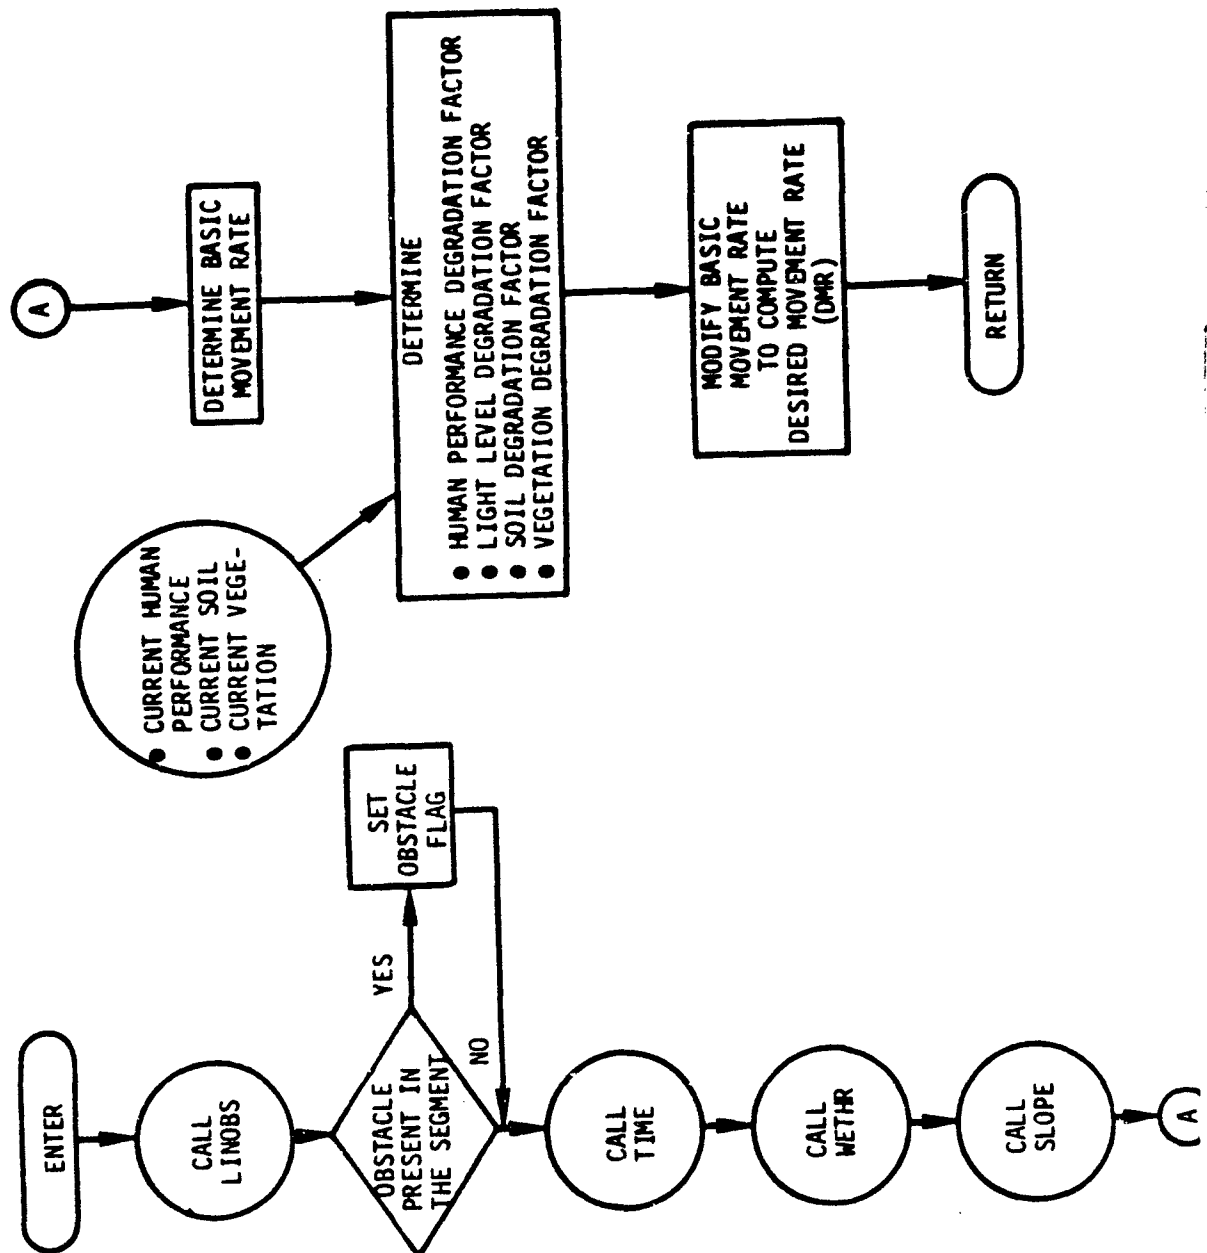

Figure 2.22, SIAF Model Threat Options

called desired movement rate, is calculated. Upon entering this subroutine, a distance segment (see Figure 2.5), based upon the minimum of the distance to a checkpoint, terrain polygon crossing, or grid crossing, has already been calculated by a segment generator subroutine (see Volume III). The first check made in this subroutine is one to determine if the segment intersects a linear obstacle. For this purpose, Subroutine LINOBS is called and an appropriate flag is set if required. After this calculation, Subroutines Time, Weather, and Slope are called as shown in Figure 2.23, and a basic patrol movement rate is determined by means of a table look-up procedure. This movement rate is then modified to account for the current human performance level of the patrol, and the current soil and vegetation the patrol is moving through (these interactions among subroutines are illustrated by means of circles in Figure 2.23). The output of this subroutine is called the desired movement rate and is defined as that movement rate consistent with good surveillance and detection capability.

Although a desired patrol movement rate has been determined in the previous subroutine, it could turn out that time contingencies require that the patrol move faster than this rate. In order to determine an actual patrol movement rate, a movement command and control subroutine, illustrated in Figure 2.24, is used. As shown in the Figure, the checkpoints from the present patrol position to the end of the patrol route are first checked to determine if there is an arrival time constraint associated with any of them. If not, the actual movement rate is set equal to the desired movement rate. If a checkpoint has an associated arrival time, then the required movement rate, based upon the distance from the patrol to the checkpoint, and the remaining time is calculated. These calculations essentially simulate the commander's estimate of his required movement rate which he would obtain in a similar manner.

Since it is possible that this required movement rate could exceed certain human and physical, environmentally constrained limits, both critical and marginal movement rate limits are next calculated. This marginal movement rate limit is defined as the minimum of the desired movement rate and a 10 percent margin associated with a movement rate consistent with zero body heat storage. The critical movement rate is defined as the minimum of three times the desired movement rate (which is

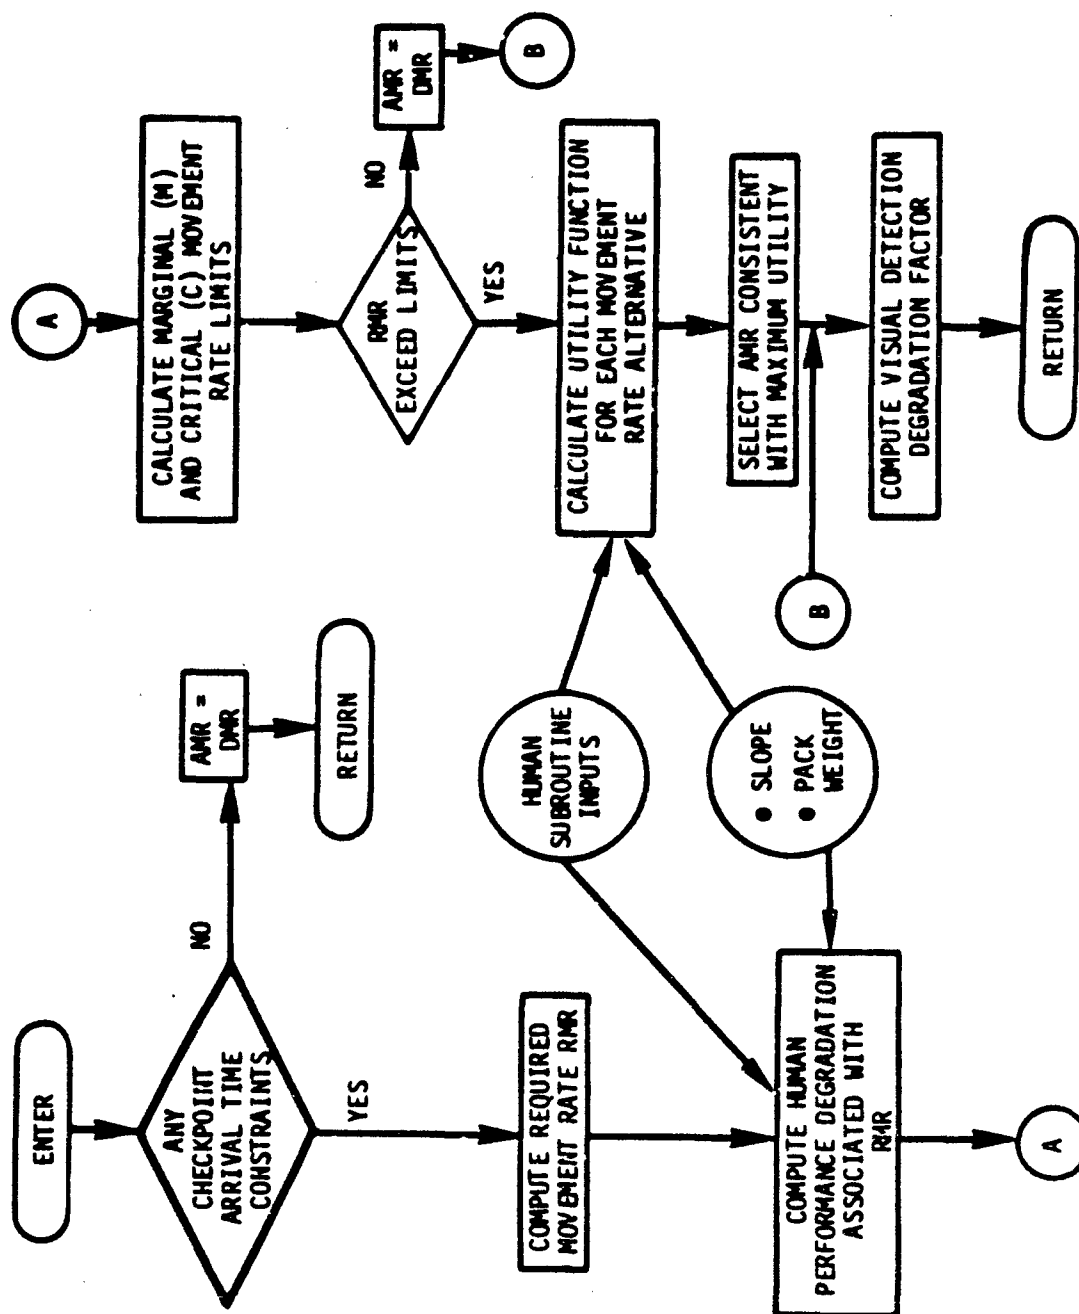

Figure 2.24. Movement Command and Control Subroutine (CRMOV1)

estimated to be the nominal movement rate due to the terrain and weather) and that movement rate at which the body just maintains thermal equilibrium. As shown in Figure 2.24, these factors are functions of the current status of the patrol which is available in the communication block of the program. If the required movement rate is less than these limits, then the actual movement rate is set equal to the desired movement rate. If the required rate exceeds these limits, then the patrol leader must trade off his surveillance capability and time. For this purpose, weighting factors for each of these performance variables are provided as input, thus allowing the user the capability to consider alternative movement rate tactics. Based upon these input weighting factors, an actual patrol movement rate is selected and the visual performance degradation factor associated with this movement rate (used by the Visual Detection Subroutine) is calculated.

#### 2.4.5 Navigation

The purpose of this subroutine is to determine the CEP of the patrol location. During the conduct of a mission, the patrol normally determines its location at the various checkpoints and reports its position to the base. However, if a target is detected or another contingency develops, the patrol may need to know its location at positions in between checkpoints. This location error is a function of the distance the patrol has traveled since it last updated its position. Figure 2.25 summarizes the calculations made in this subroutine which starts by computing the range and azimuth errors associated with navigation from the last checkpoint. These dead-reckoning errors are then combined with map, base, and recording errors, and a basic patrol CEP is calculated. Next, the user has the option of adjusting this calculated CEP in accordance with the specifications provided in Reference 2. Independent of these specifications, the patrol could improve its initial estimate of its location by map terrain association if the light level is favorable. This essentially adjusts the location estimate to account for readily identifiable terrain features which the patrol leader could use to more accurately determine his position. Finally, the user has the option of specifying certain patrol location equipment which aids the patrol in determining its position. If this equipment is specified, then the patrol location is adjusted, based upon the amount of

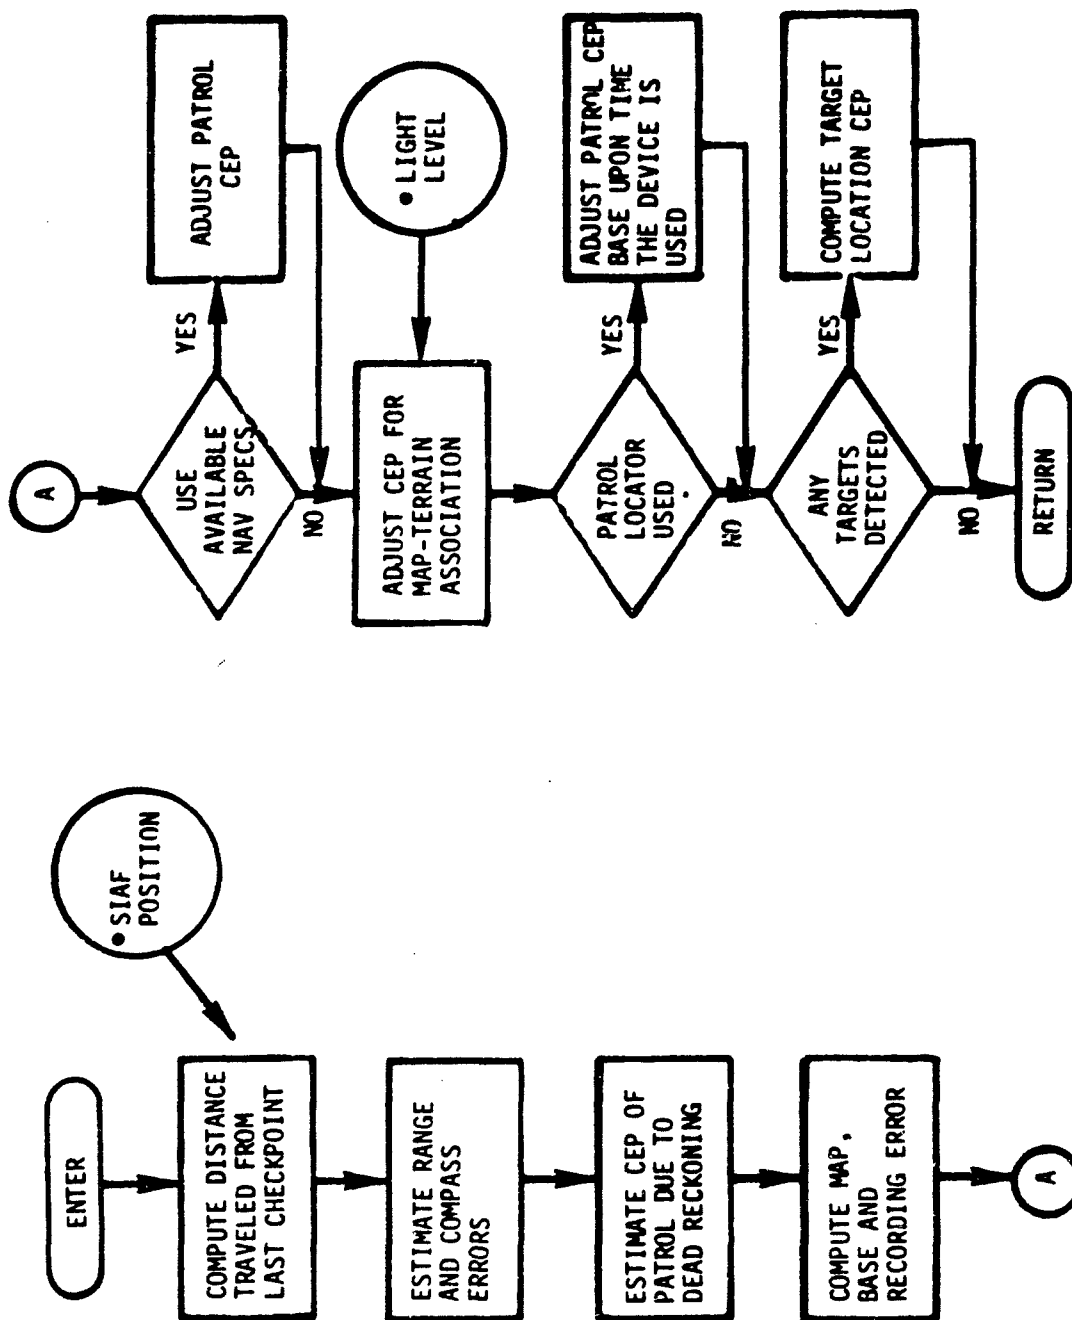

Figure 2.25, Navigation Subroutine (NAV)

time this equipment is used. These steps serve to determine a CEP of the patrol location. As shown in Figure 2.25, if a target is detected, this subroutine also calculates the CEP of the location of the target with respect to the patrol. This calculation is based upon considerations similar to those previously described.

#### 2.4.6 Surveillance/Detection

##### Aural Detection

The purpose of this subroutine is to determine an aural detection verdict for SIAF against the targets in the area of operations and for the targets against SIAF. The aural detection capability of an individual depends upon the local background sound level and the sound level being made by the individual. The first calculation made in this subroutine, shown in Figure 2.26, is to determine the local aural background level for SIAF and for the targets. This background level is a function of the vegetation, time of day, and weather. Next, the source noise level for SIAF and the targets is computed. This source noise level depends upon the number of men in the unit, their disposition, and their present activity. If, for example, the patrol is moving through heavy vegetation, then its source noise level is considerably higher than it would be if the patrol were conducting a stationary reconnaissance. Based upon these two calculations, the sound level arriving at the listener is computed (considering range and vegetation attenuation) and is compared with the hearing threshold and the local background noise. If the threshold is exceeded, then the appropriate detection opportunity is stored in a vector for subsequent analysis by the Detect and Decision Subroutines.

##### Visual Detection

The Visual Detection Subroutine is illustrated in Figure 2.27. The purpose of this subroutine is to calculate probability of making a single glimpse, visual detection of targets that are feasible of being detected by SIAF, and for targets to detect SIAF. In this calculation, line of sight between SIAF and the targets is assumed. Hence, the calculation mainly considers light level for the detection computation. As shown in Figure 2.27, the first calculation is to determine the target reflectance, background reflectance, the light level at the target, and the light level

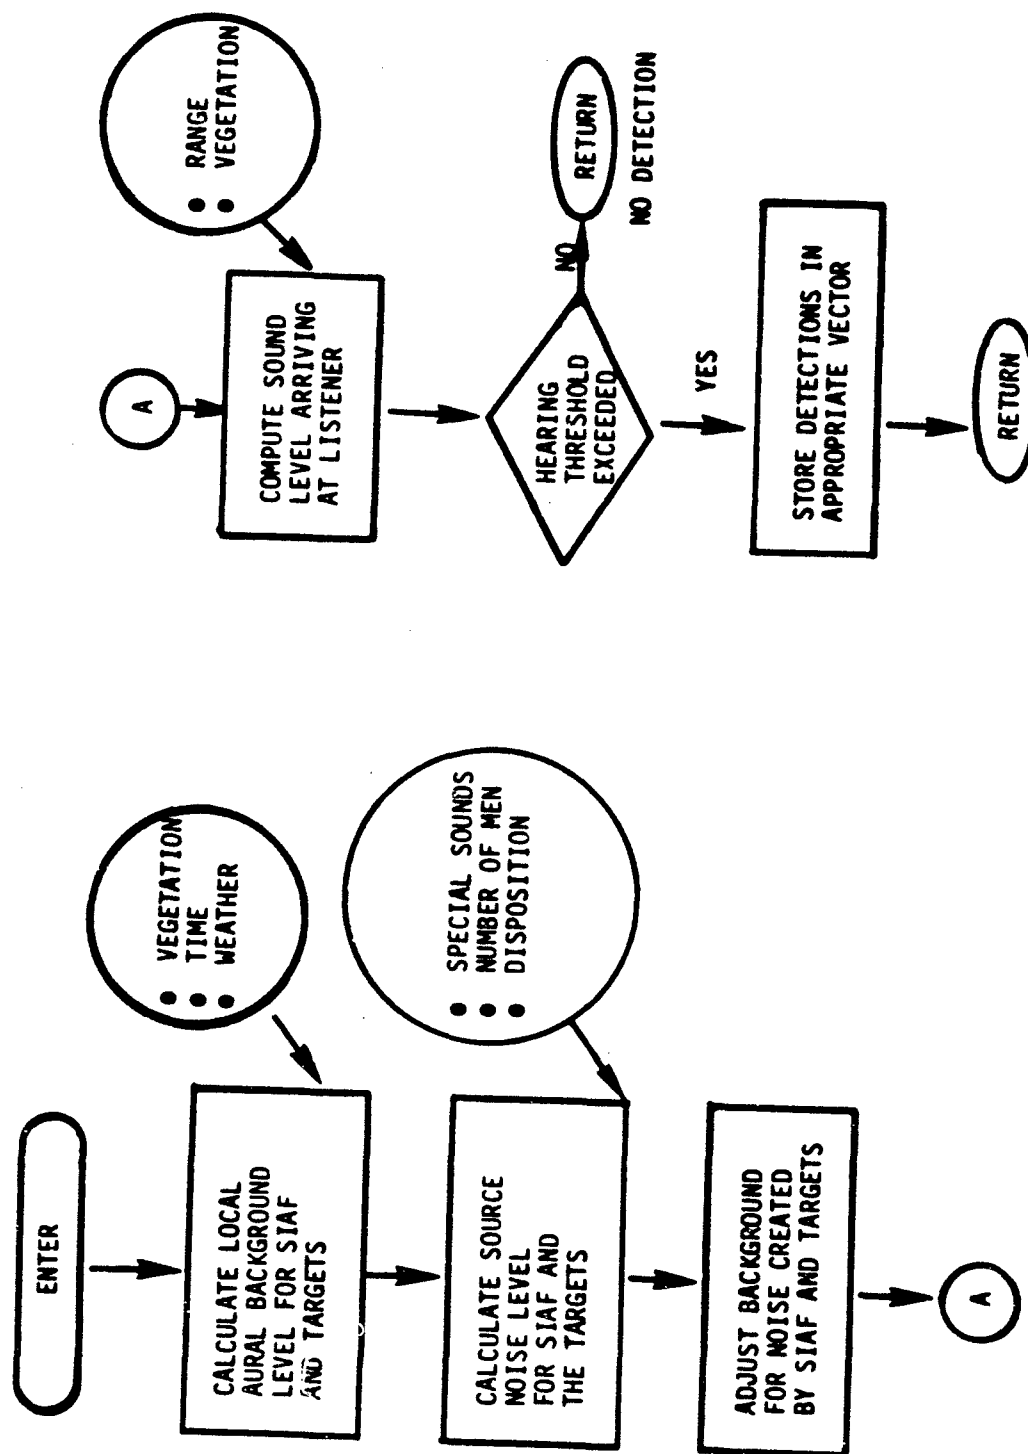

Figure 2.26, Aural Detection Subroutine (AURAL)

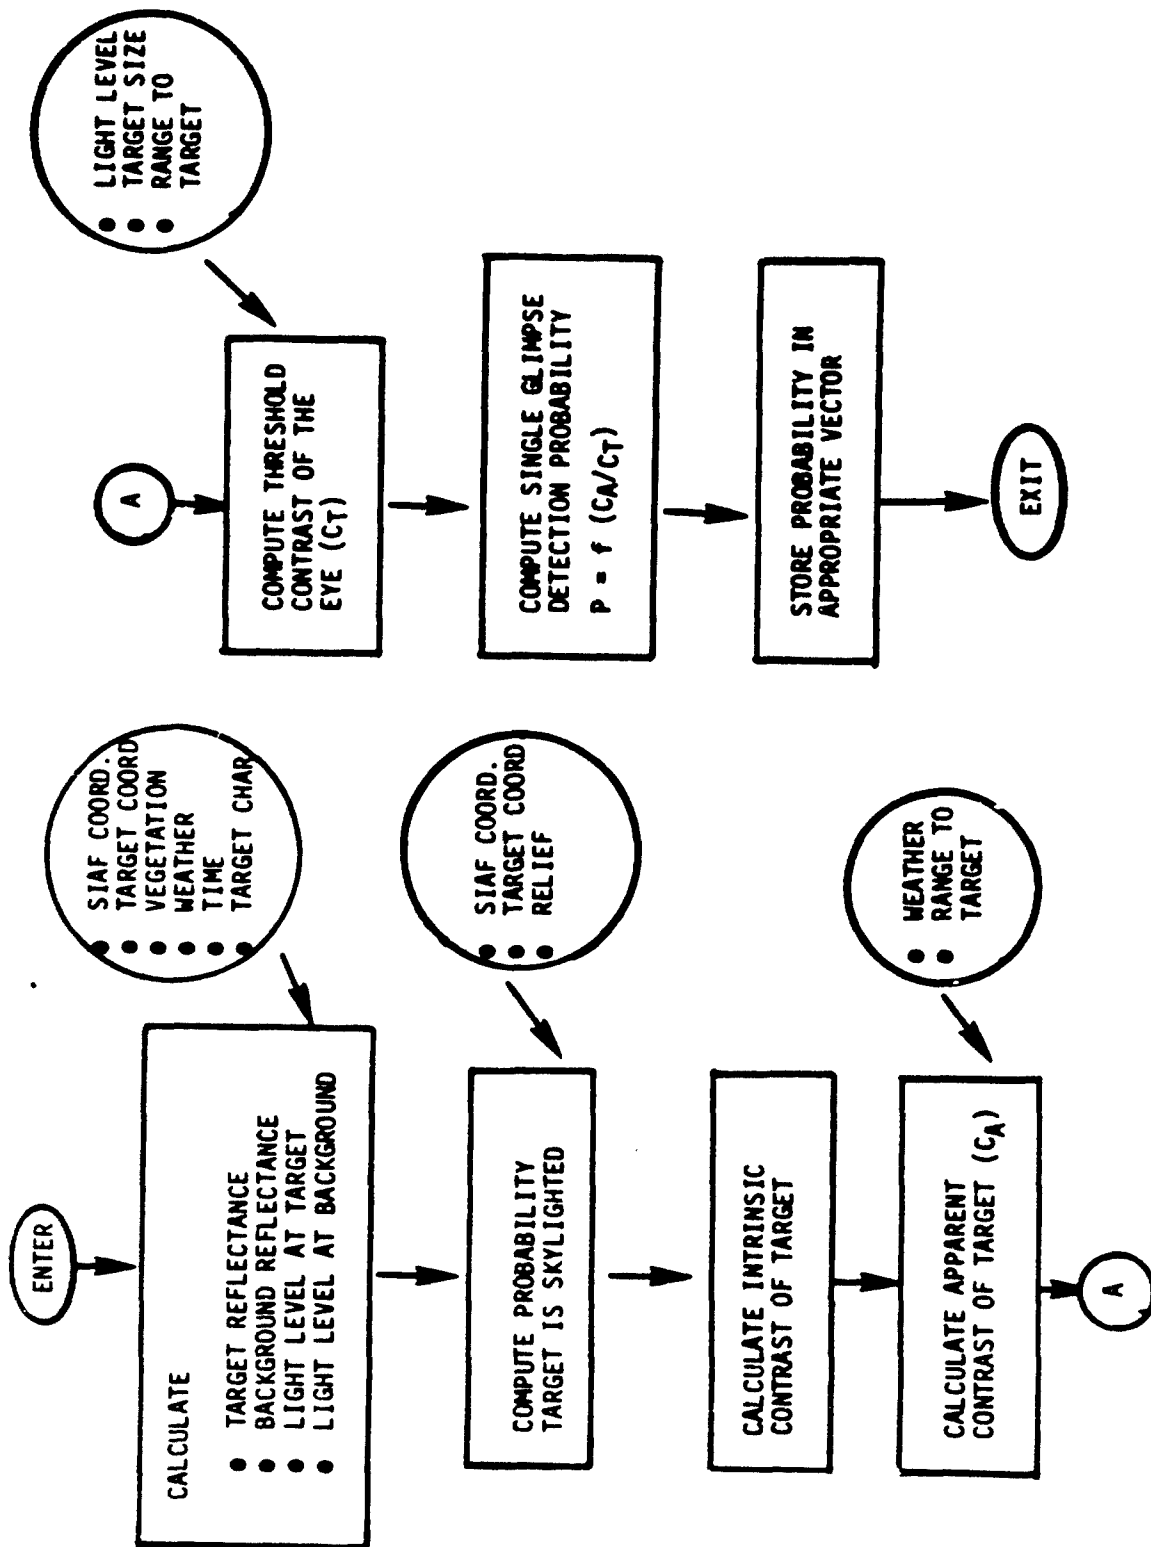

Figure 2.27. Visual Detection Subroutine (VISUAL)

of the background. Depending upon the location of SIAF and the particular target under consideration, there is a possibility that the target may be skylighted. The next calculation is then made using the Terrain Concealment Subroutine to determine background conditions, including skylighting. Based upon this information, the intrinsic contrast of the target is computed. This intrinsic contrast is essentially the ratio of the brightness of the target to the brightness of the background. Depending upon the range between SIAF and the target and the weather conditions, the contrast of the target as observed by the eye differs from the intrinsic contrast. This is called apparent contrast and is next calculated considering the factors mentioned above. The third contrast calculated in this subroutine is threshold contrast of the eye. As indicated in Figure 2.27, this threshold contrast is a function of the light level, target size, and the range to the target. The ratio of apparent contrast to threshold contrast is then used to determine a single glimpse detection probability. This probability is then stored in an appropriate vector as further indicated in Figure 2.27.

#### Detect

The described calculations serve to determine detection opportunities and are independent of line of sight. Subroutine Detect, illustrated in Figure 2.28, combines these calculations with the relief and vegetation and considers the physical location of SIAF and the target. As mentioned previously in Section 2.3, this detection calculation is made once for each mini-segment and can consider man-to-man detection if desired by the user. The first calculation made is to determine which patrol members are looking in the correct sector to potentially see the target. If, for example, no patrol members are viewing any targets, then detection is not feasible. For all feasible targets, Subroutines TERCON, AURAL, and VISUAL are next called. These subroutines essentially examine line of sight between SIAF and the target, sound levels made by SIAF and the target, and light level to determine whether detection or several detections can possibly occur in the mini-segment. Based upon this information and the time available, detection verdicts are calculated in a Monte Carlo fashion for SIAF and all detectable targets. The order and interval between detections is created to identify who sees who first and later is used in the decision model to determine simultaneous detection/counterdetection situations.

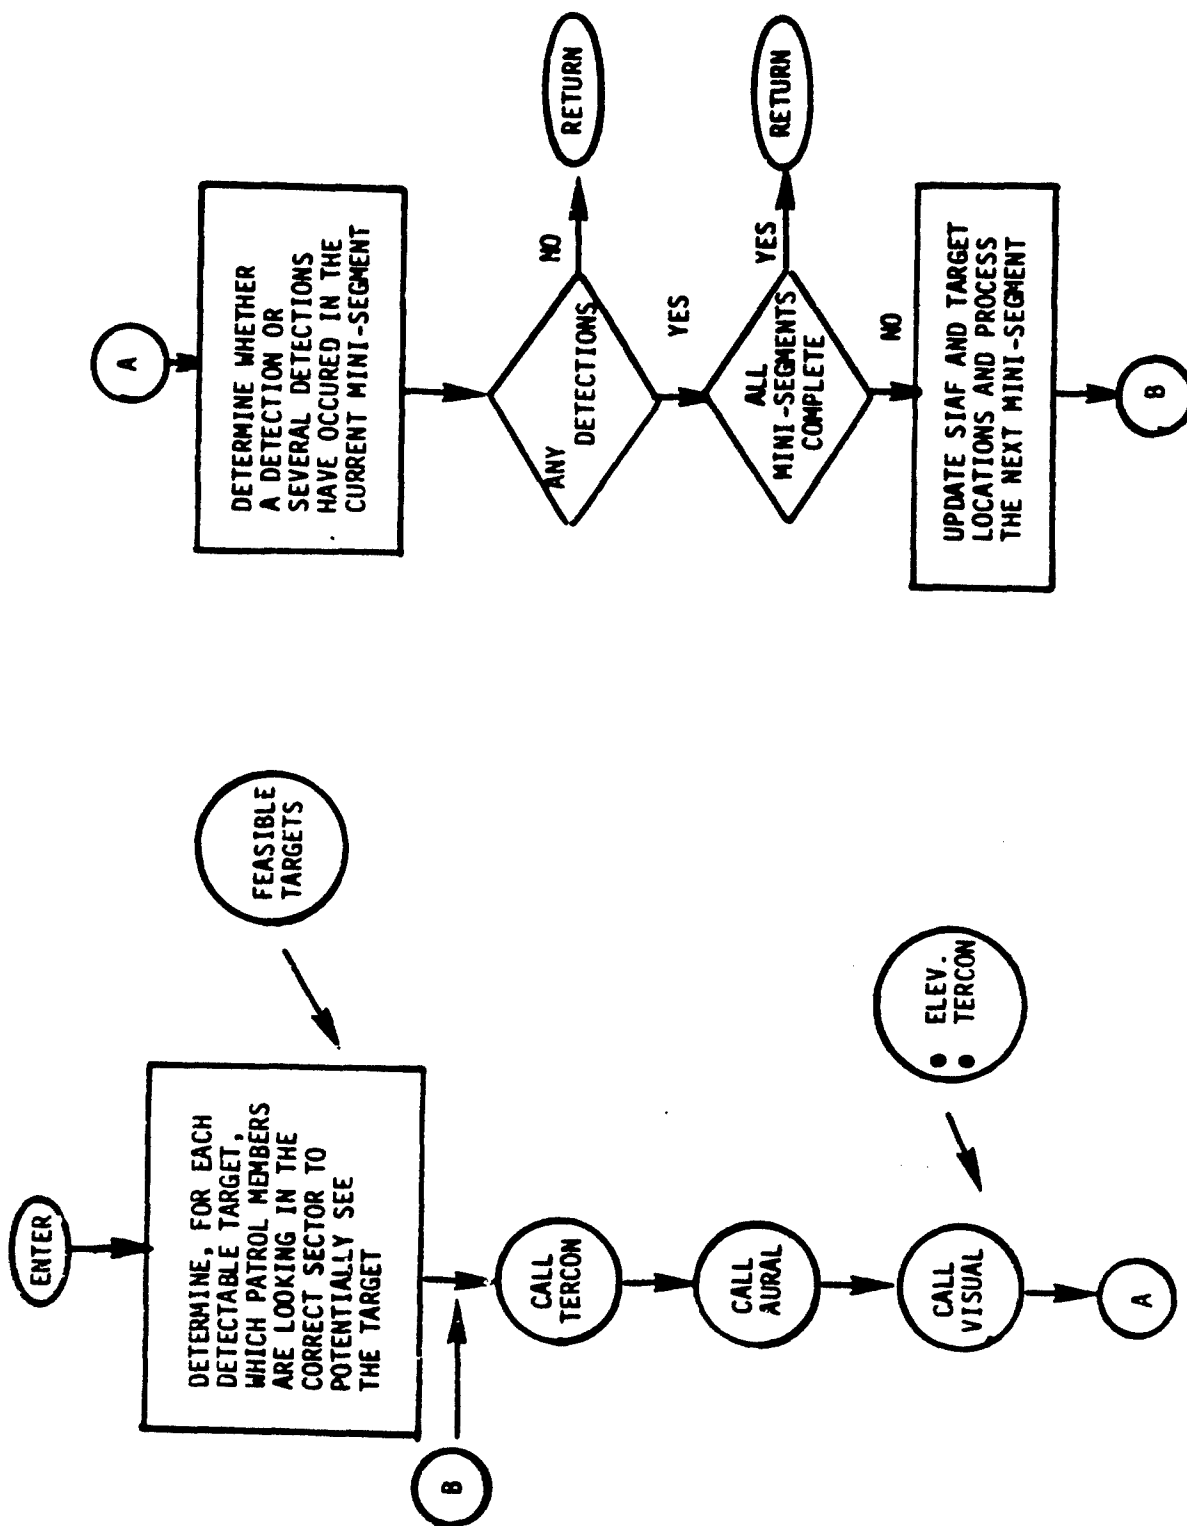

Figure 2.28, Detection Subroutine (DETECT)

#### 2.4.7 Fire Support

If a patrol detects a target, it may elect to direct fire on the target, without engaging in a firefight depending upon the mission and the situation at the time of detection. For this purpose, an external fire support subroutine (EPS) is called by the Executive Routine. As shown in Figure 2.29, the user can select air, artillery, or manual gunfire for analysis. If air is selected, then the assumption is made that the target movement provides negligible error in ordnance delivery CEP. Because of the response time of artillery and naval guns, a moving target could introduce decreased accuracy in delivery CEP; hence, the user can examine this situation if desired. As shown in Figure 2.29, factors such as surprise and adjusted fire, target reaction to the first round hit, and the interactions of the effectiveness of the fire support mission with the patrol and target location errors are considered. If preliminary fire support is to be used prior to attacking a target, a detailed simulation of external fire support effectiveness is used. This is discussed in the Combat Submodel description.

#### 2.4.8 Supply Maintenance

The Supply Maintenance Subroutine illustrated in Figure 2.30 is essentially a booking subroutine which increments and/or decrements the supply status of the patrol during each segment. As shown in the Figure, food, water, ammunition, and pack weight are incremented if the patrol was resupplied during the last segment and decremented for combat operation and for normal food and water consumption. The normal food and water consumption requirements are calculated in the Human Maintenance Subroutine which follows.

#### 2.4.9 Human Maintenance

This subroutine computes food and water requirements for the patrol and calculates the current human performance degradation of the patrol. As illustrated in Figure 2.31, the current energy expenditure rate of the patrol members is first determined. This is based on the current patrol activity which includes rest, sleep, stationary reconnaissance activities, or movement. During movement, the energy expenditure rate is a function of the slope, pack weight, and movement rate, for which values are available to this subroutine via the communication block of the program. Once the energy expenditure rate is determined, the value of the segment time is used

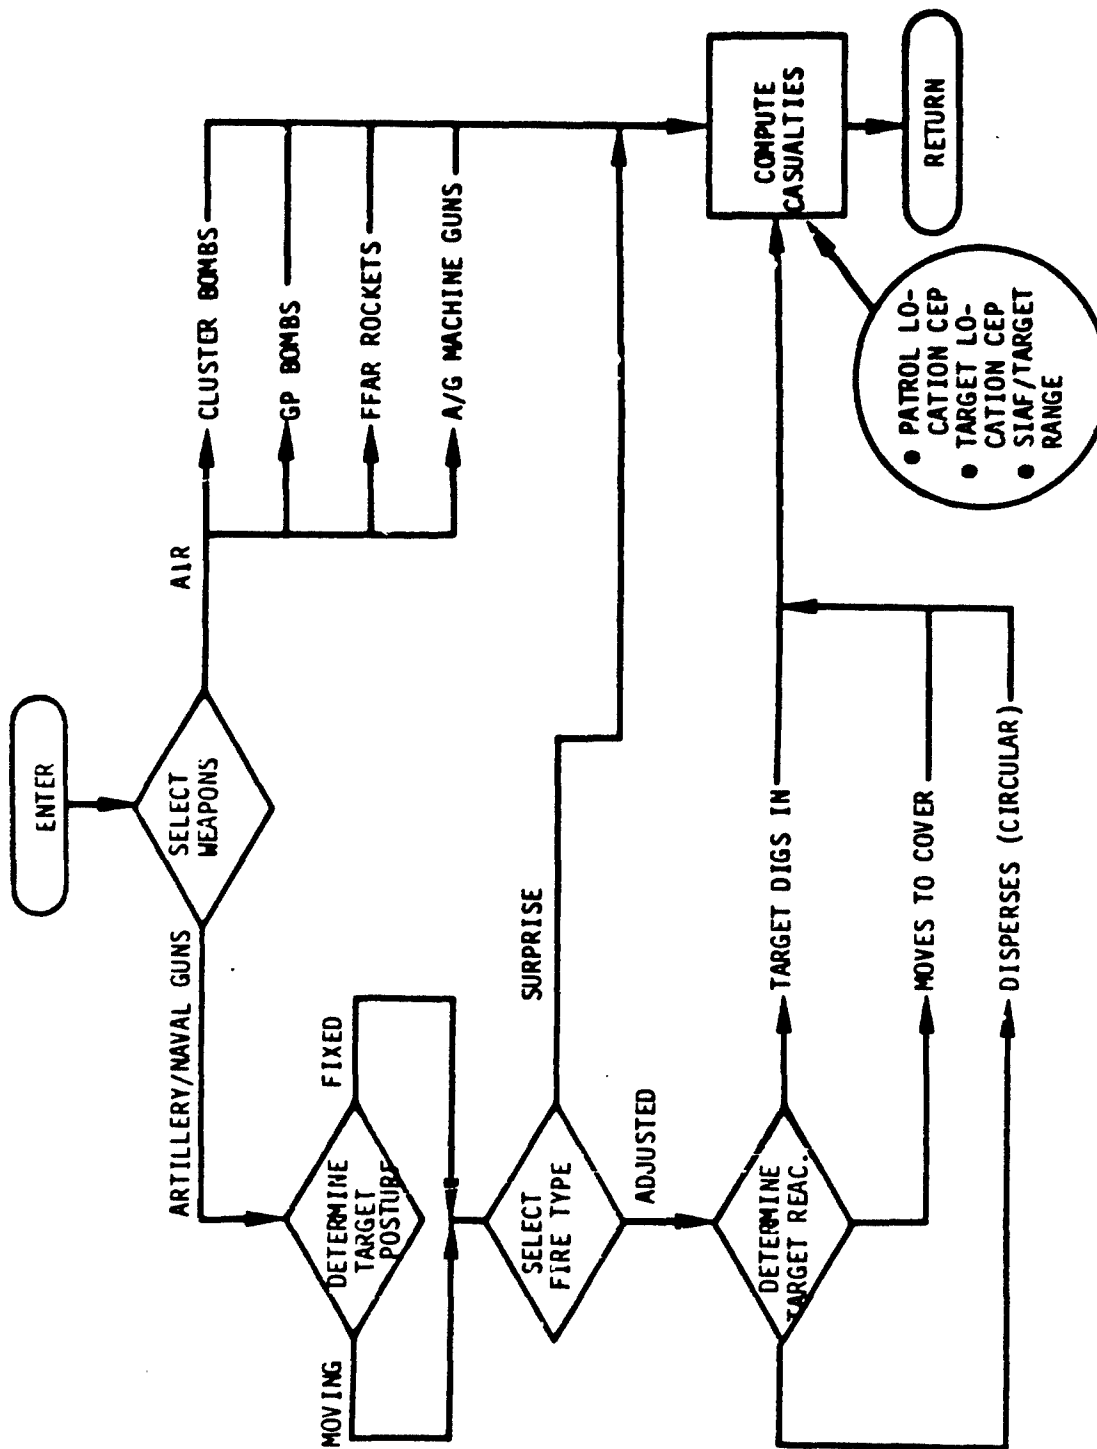

Figure 2.29, External Fire Support Subroutine (EFS)

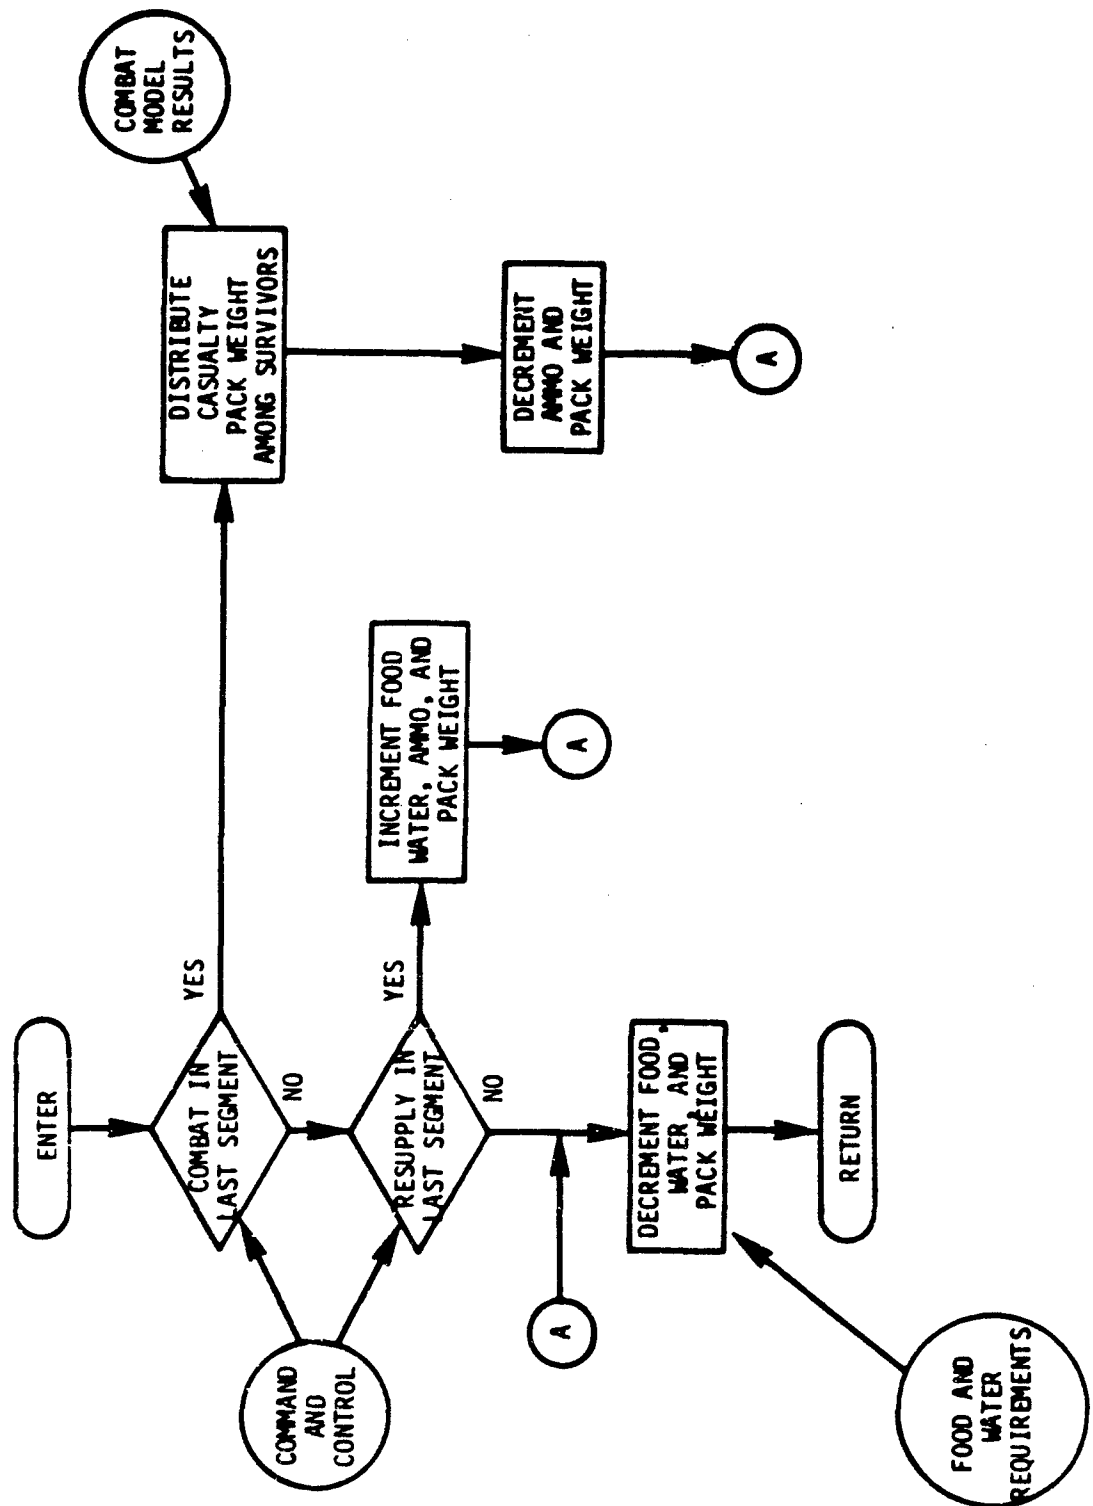

Figure 2.30. Supply Maintenance Subroutine (LOGIS)

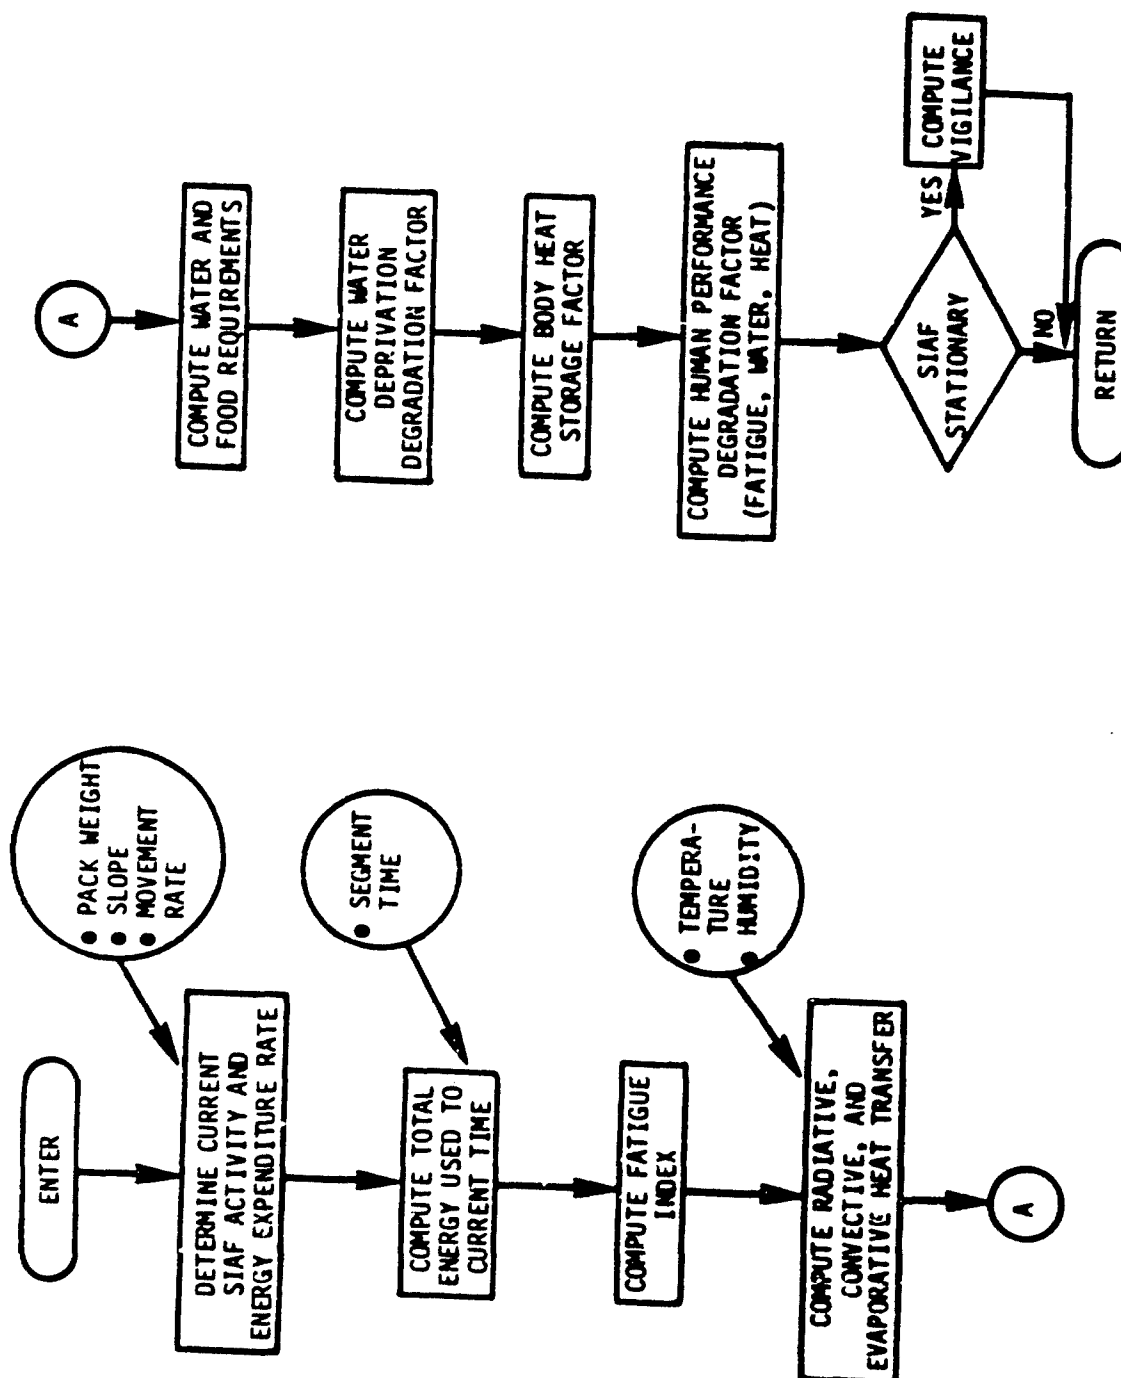

Figure 2.31, Human Maintenance Subroutine (HUMAN)

to compute energy expenditure and an associated fatigue index as shown in Figure 2.31. This energy expenditure is then used to compute the body heat lost through radiation, convection and evaporation. From this, food and water requirements and body heat storage are calculated. These factors are then combined and a human performance degradation factor is computed. This human performance degradation factor is the amount in percent by which the performance of patrol functions such as visual detection are degraded due to fatigue, body heat storage, and water deprivation. In addition, visual detection performance is influenced by a factor called vigilance which accounts for the decrease in the alertness of patrol members as a function of the time they have been conducting stationary reconnaissance operations. If the patrol is stationary, this calculation is also made as shown in Figure 2.31.

#### 2.4.10 External Communications

The External Communications Subroutine shown in Figure 2.32 calculates an external communication verdict for the patrol on each communication attempt. First, the total ampere hours currently available to the patrol are computed to determine if the battery life is expended. If so, a no-communication verdict is returned by the subroutine. If power is available, then a power budget analysis is conducted; and vegetation, defraction, and space losses are computed. These calculations depend upon the current distance from the patrol to the base and the terrain between SIAF and the base. The results of this power budget are used to compute the signal-to-noise ratio at the receiver. This signal-to-noise ratio is then used to compute message intelligibility. As shown in Figure 2.32, the model simulates the actions of the patrol repeating the message until the intelligibility criteria (a user input) is satisfied. If the intelligibility criteria is not satisfied with N trials (N is a user input), then a no-communications verdict is returned by the subroutine. If the criteria is satisfied, then the communication is said to be successful.

#### 2.4.11 Command and Control

The current SIAF command and control model consists of a movement command and control subroutine (described in Section 9.1) and a post detection decision subroutine (Section 9.2).

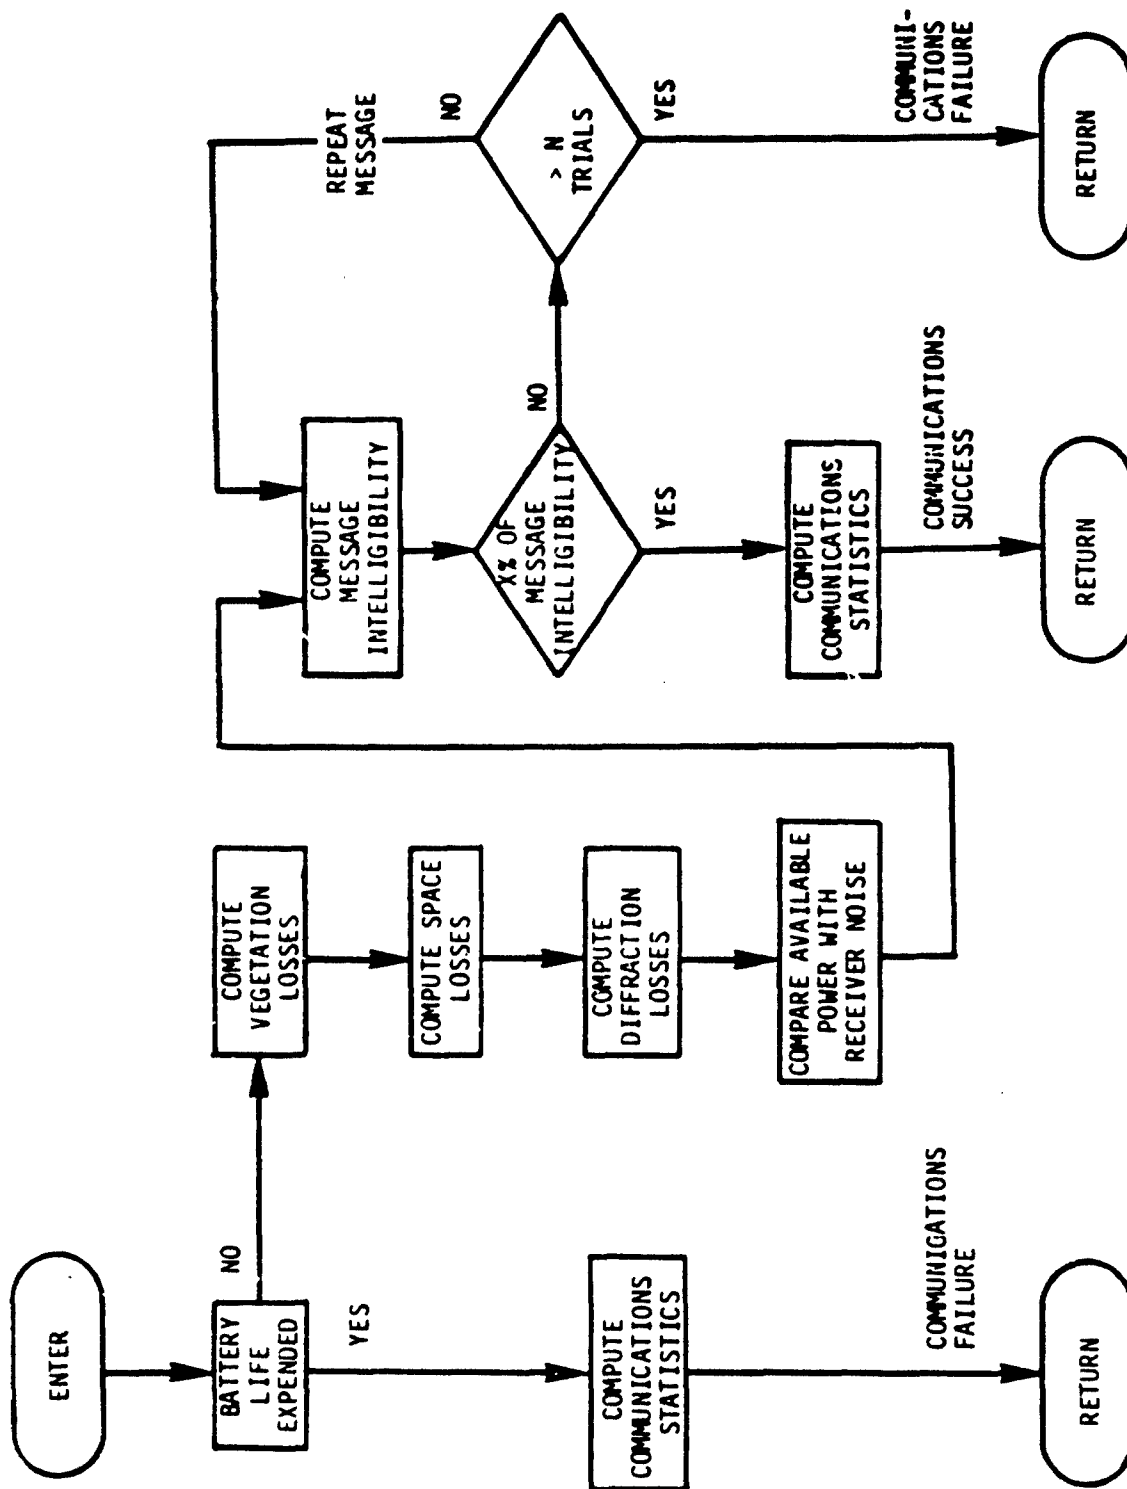

Figure 2.32, External Communications Subroutine (EXCOM)

With respect to patrol movement, the required movement rate which a patrol must sustain in order to arrive at a next checkpoint on time is compared with a desired movement rate that is consistent with being able to maintain good surveillance. If the required rate exceeds the desired rate, trade-offs are made between time and detection performance to select the most satisfactory movement rate for the patrol. The trade-off results can be controlled by adjusting input weighting factors.

In the post detection subroutine of Section 9.2, alternatives are provided which cause the patrol to move along a dynamic route toward the target to identify it or to move around the target to avoid it. Logic is also provided for calling external fire support on targets. Input variables are provided which allow the user the capability of exercising these model options (see Section 9.0 for details).

## 2.5 SIAF COMBAT SUBROUTINES

Thus far an overview of the reconnaissance model has been presented in previous sections. Once the SIAF patrol detects a target, however, it may decide to combat the target, and once the combat is completed the patrol may decide to continue the reconnaissance mission. The SIAF model considers these possibilities. In the following section an overview of the combat decision and execution subroutines are presented. (Details of these routines are described in Volumes V and VI.) Included is a description of the decision logic and decision optimization routines, and a discussion of the combat executive routine. Finally an overview of the withdrawal and the continue mission routine which allows the patrol to continue on its reconnaissance mission once the combat operating is completed, is presented.

### 2.5.1 Combat Decision Logic and Optimization Logic

In the SIAF reconnaissance model many detection and identification possibilities exist. For example, the SIAF patrol could possibly identify two targets simultaneously or several targets could identify and detect SIAF at the same time. Because of the complications involved in developing logic to model these situations, combat operations where more than one target is involved are not considered in the model. Instead if it turns out that several targets detect SIAF or SIAF has detected and identified several targets then a no combat decision is made and the SIAF patrol avoids the

Revised December 1973

targets. Considering the fact that SIAF normally operates as an independent force this is probably a reasonable simulation of what they would in fact do. That is, should they detect and identify more than one target they would probably avoid the target area.

Now consider the case in the simulation model where SIAF detects and identifies a single target. In this case if its mission is combat, the patrol must decide what kind of combat action to initiate. Here decision logic is necessary since it is impossible to determine exactly where the patrol will be and exactly what and where the target is when the detection occurs during the simulation. Hence this logic dynamically examines the current tactical situation and selects a course of action. The movement to contact and deployment decision logic shown in Figure 2.33 indicates that five courses of action are possible. The first course of action is that the patrol could call in external fire support on the target. The second alternative is that the patrol could deploy for ambush. This alternative, for example, would probably be selected if the target were moving toward the SIAF patrol. On the other hand the target may be moving in a direction away from the patrol or may be out of range of the patrol. In this case the SIAF patrol could decide to move to a deployment position and call for external fire support if available, before initiating the fire fight. Another alternative, even before a detection occurs, is to move to an ambush area to deploy Claymore mines. The fifth alternative, of course, is a no combat decision. The decision logic subroutines examine the current tactical situation and select one of these alternatives based on the following decision variables.

- 1) Mission (ambush, attack, or deploy Claymore mines)
- 2) Force ratio (i.e., the relative size of the target vs the size of the SIAF)
- 3) SIAF-target range
- 4) Direction of travel of the target
- 5) The terrain between the SIAF patrol and the target as to its effects on cover, concealment, and observability.

The decision logic is constructed so that the user can adjust the input data and choose different criteria for selecting a course of action. Thus the decision variables are examined, the tactical situation determined by the model and a combat option is dynamically selected.

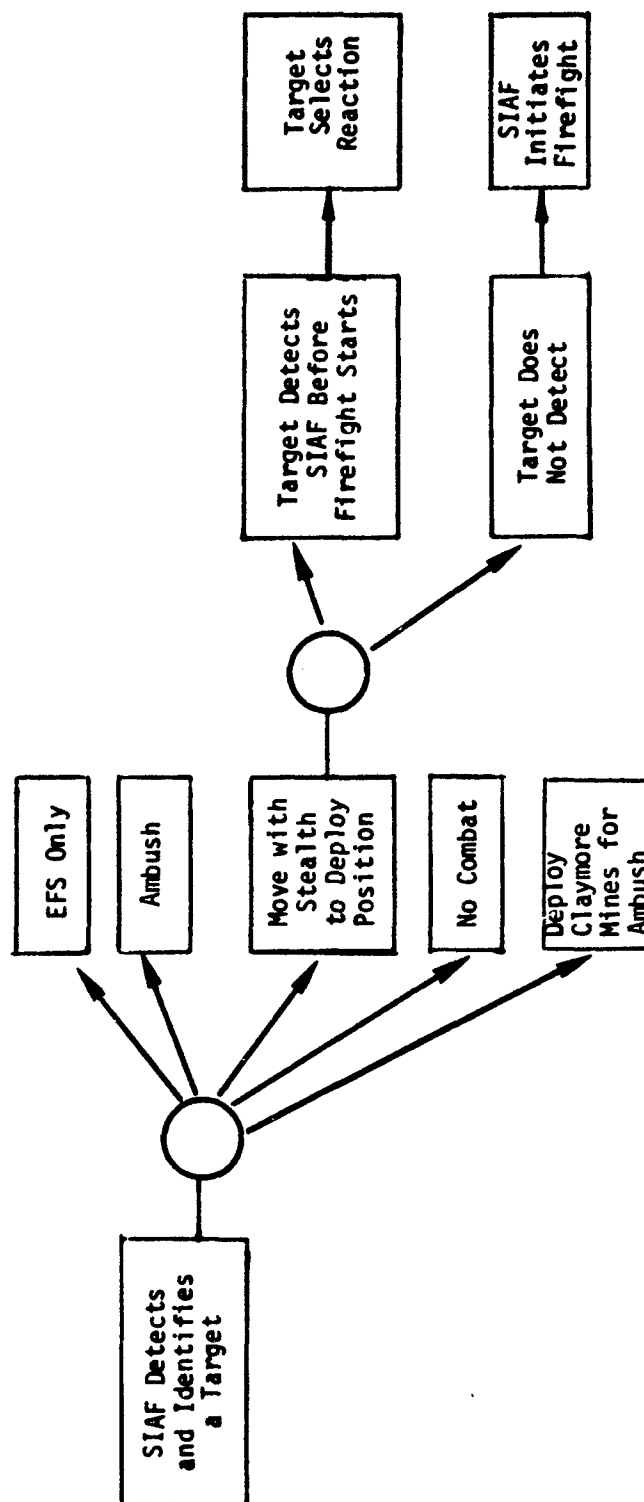

Figure 2.33, Movement to Contact and Deployment Logic

In the case of external fire support only the external fire support (EFS) subroutine is then called, external fire support simulated, and the patrol then makes a "continue the mission" decision and would probably, in this case, decide to return to continue the reconnaissance patrol. In the case where deployment is selected, optimization logic optimally selects the exact deployment position of each maneuver unit in the terrain. The most complicated situation evolves when the patrol decides to move to a deployment position. In this case the dynamic route selector routine (DROUTE) selects movement points based upon different movement criteria which again are user input. As shown in Figure 2.33 when the patrol is involved in this type of a movement the target could possibly detect the patrol before the fire fight occurs. In this event the target could react by moving, deploying, or opening fire. If, on the other hand, the target does not detect the patrol in movement to the deployment position, SIAF initiates the fire fight. If the target should move toward a better defensive position, the SIAF may reselect its deployment points or exchange roles between maneuver units and and the base of fire. Thus, the combat decision and optimization logic provide a mechanism for the user to select various combat alternatives based upon the current tactical situation.

#### 2.5.2 Combat Executive

In Section 2.3 the executive routine used to drive a reconnaissance model was described. In this section an overview of the executive routine used to drive the combat model is presented. In this regard two approaches for driving the combat executive routine were examined. The following section describes and compares these two approaches.

The first alternative shown in Figure 2.34 indicates that each man in this situation has a clock time, initial values of which are selected to be different based upon user input. The model selects the man with the smallest clock time and decides how much time is to be spent observing in an intelligence routine, and computes this amount of time ( $t'_1$  in the figure). Then movement and fire controller models decide if the man will move or fire. If he is to fire, for example, the fire controller model decides at whom he will fire and computes the firing time ( $t'_2$  in the figure). If communications are to occur the time required for communications are also computed. Finally casualty assessments are made. After these calculations are made the clock time for this particular individual examined

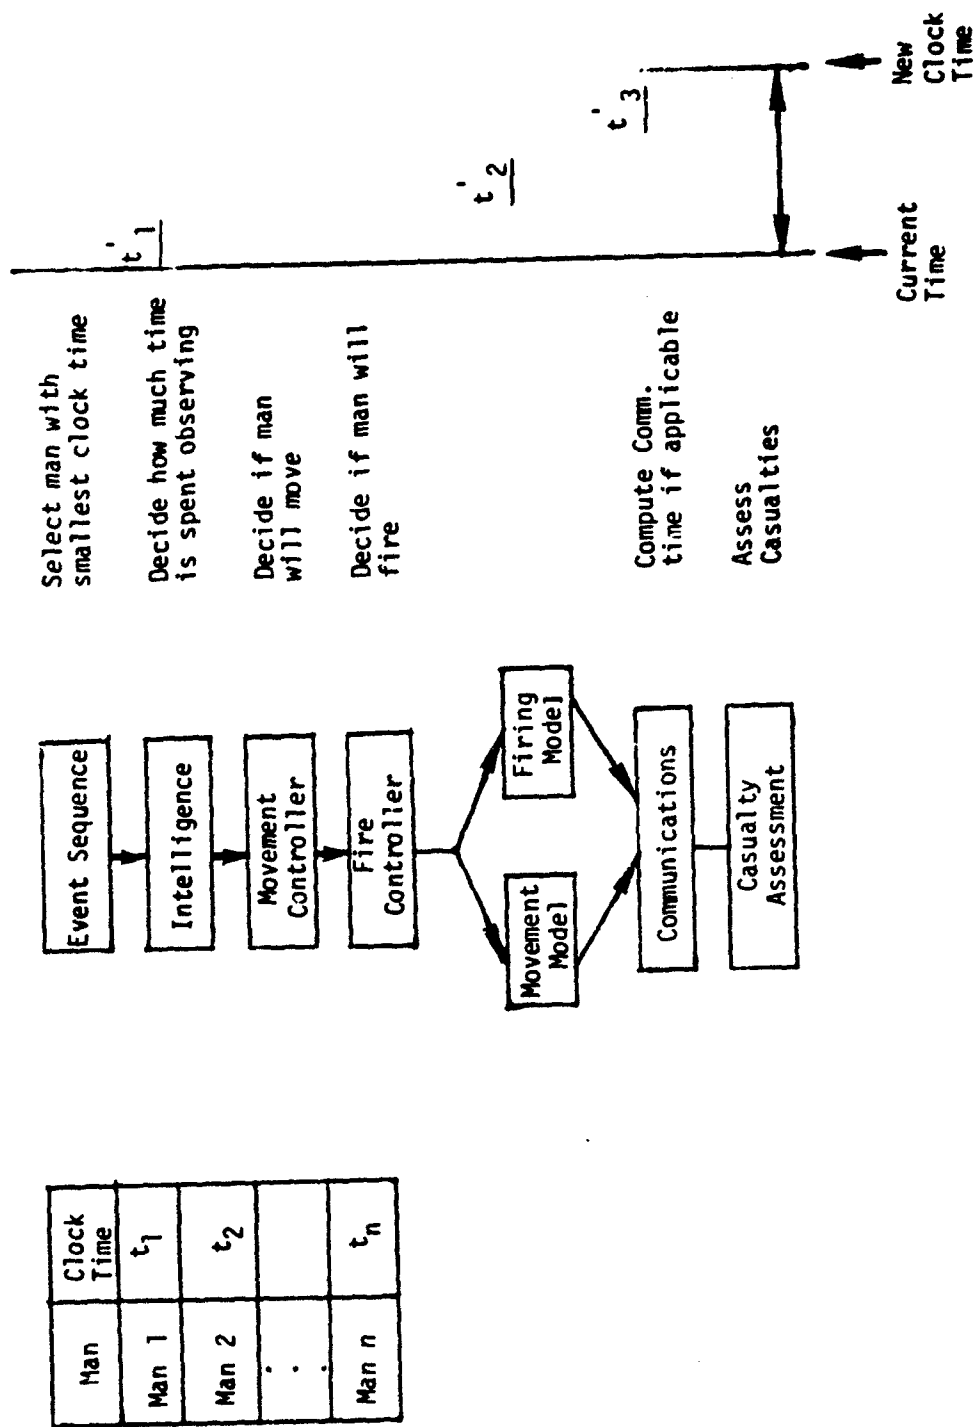

Figure 2.34, Alternative 1 to the Combat Executive

is advanced by the amount  $t'_1 + t'_2 + t'_3$  and he is given a new clock time. The model then scans the list of men and clock times, picks out the minimum, and repeats the procedure. Thus, in alternative one, each man is individually cycled through functions that he is required to perform during combat and time is advanced in the fashion described above. This is the approach that is used in models such as DYN TACS and ASARS.

An alternative to this approach is presented in Figure 2.35. Here, instead of individually selecting each man and having a clock time associated with each man, only one clock time exists in the model. The event times in this case are movement, detection, casualty, EFS burst, and internal message reception. The executive routine computes the movement and detection event times for each individual for both the attacker and defender, and the casualty times of each individual for both the attacker and defender. It then scans this list of times together with any scheduled arrival of EFS and any scheduled reception of a message between maneuver units. It then selects the minimum time, and defines the corresponding event as the event which occurs in this particular segment of the model. Figure 2.35, for example, illustrates what would happen if the event were movement. In this case, all moving individuals would be moved an appropriate amount of ammunition, the clock time and the status of each man would be updated, and calculations would be repeated. Thus, instead of cycling through each man, this particular method examines the next event to occur for all men, advances the clock time based upon the minimum of these times, and updates the attributes of each man to what they would be at this time.

A comparison of these two approaches is shown in Figure 2.36 and here, three attributes were defined: running time, event accuracy, and capability to handle cumulative interactions. The comparison indicates that alternative one probably has a faster running time in most cases. However, arguments that alternative two could be faster are also possible to evolve. As far as event accuracy is concerned, alternative one could possibly neglect events which occur to other individuals during a given loop through the logic. The reason for this can be seen through a further examination of Figure 2.34 which shows that an individual could possibly become a casualty during the advance of his clock time. Thus, unless a time step variable is set to adjust the advance of

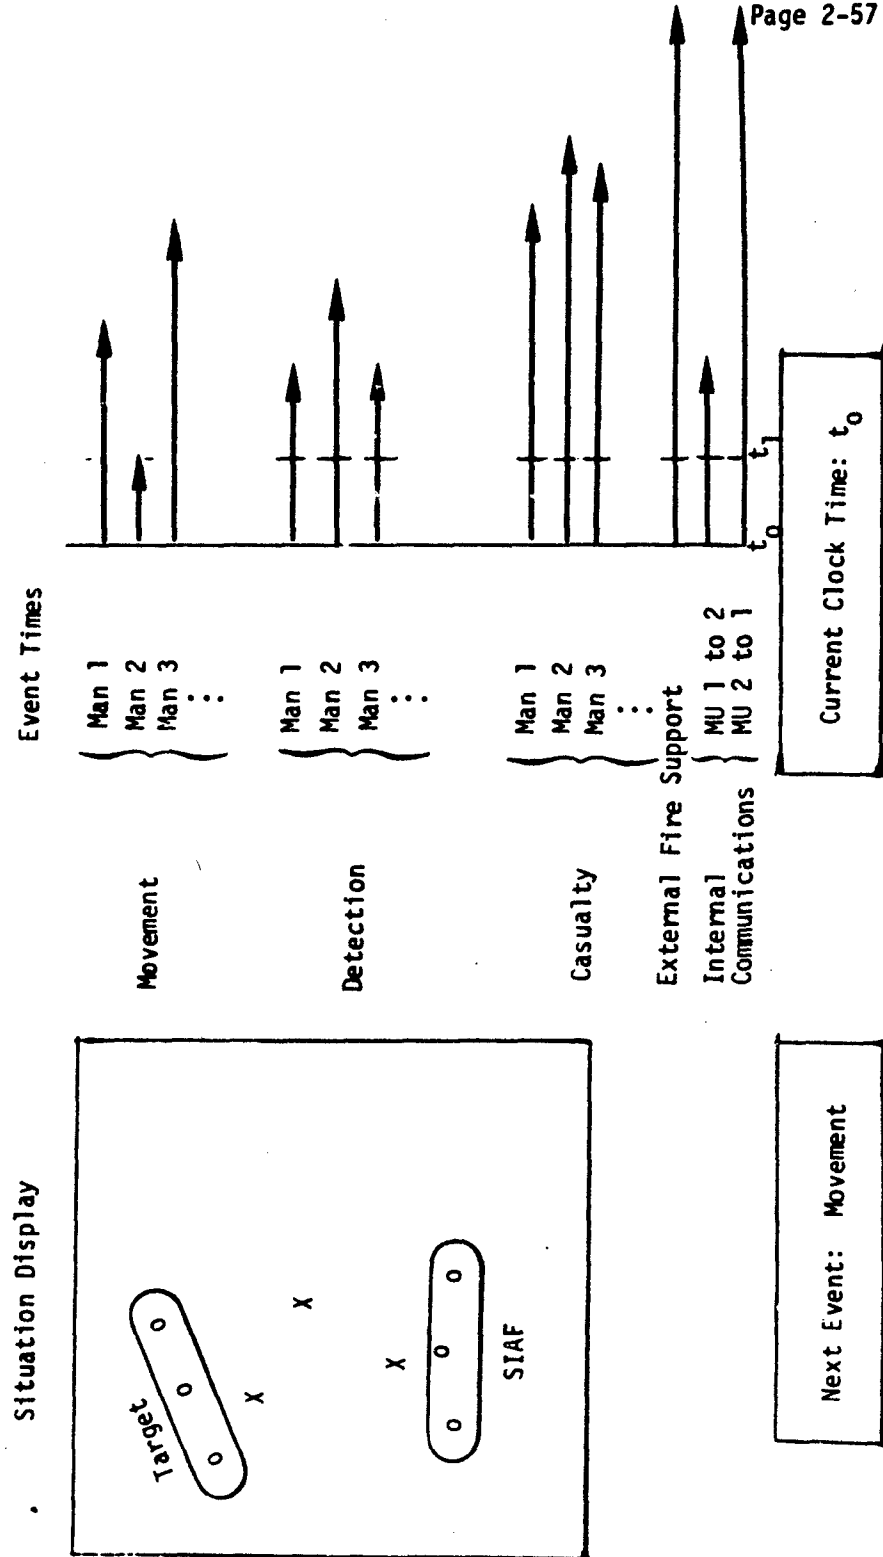

Figure 2.35, Alternative 2 to the Combat Executive (Sheet 1)

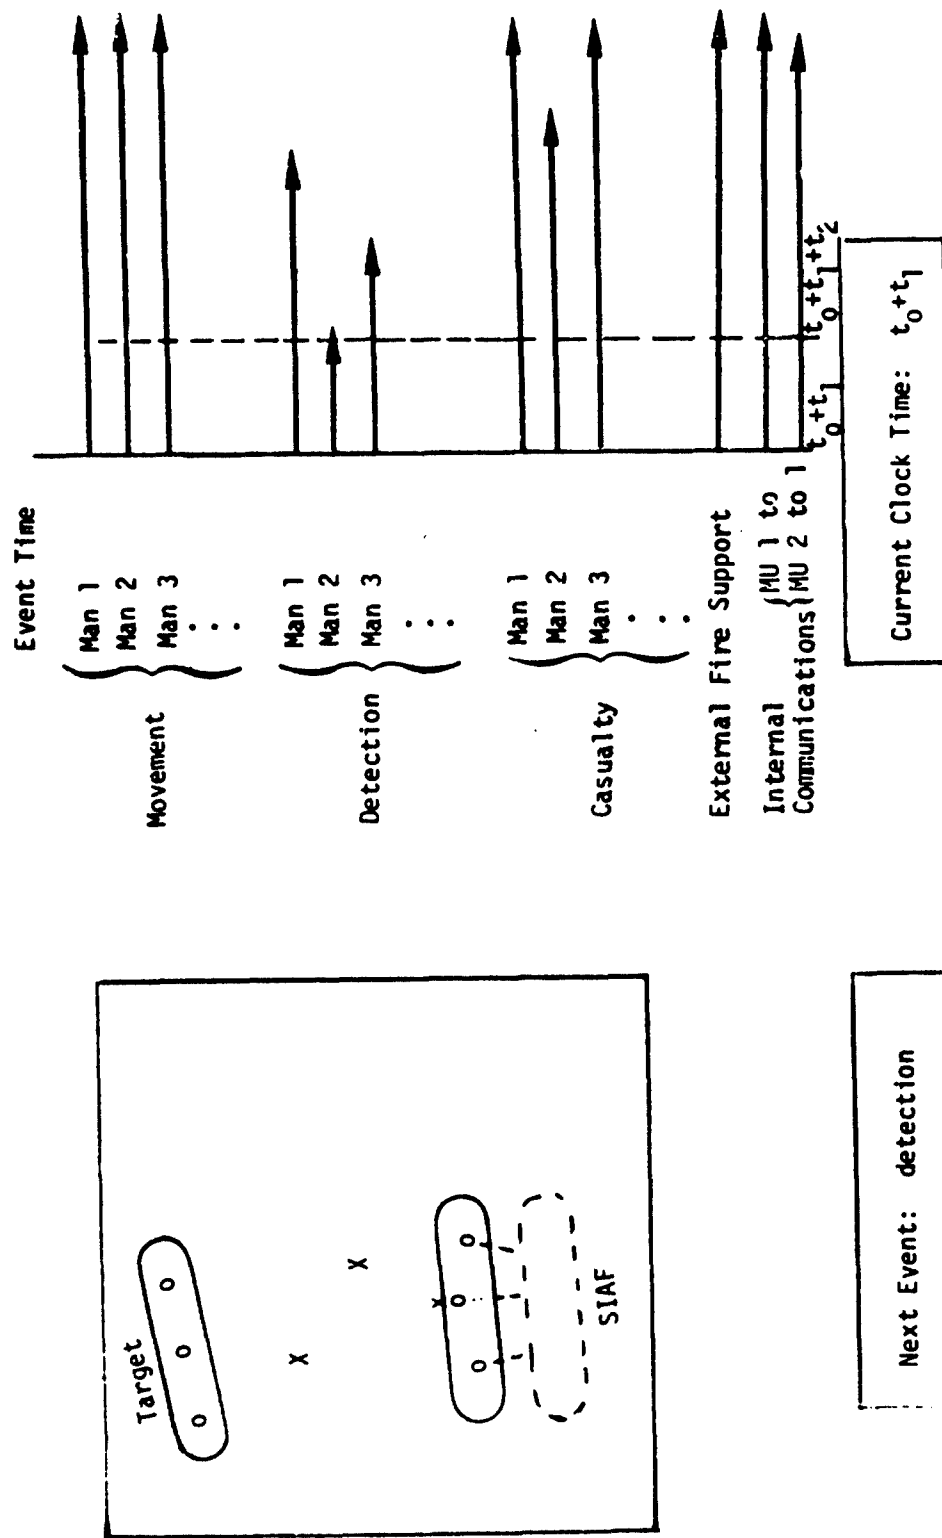

Figure 2.35, Alternative 2 to the Combat Executive (Sheet 2)

| Attribute                                 | Alternative 1   | Alternative 2<br>SIAF Technique  |
|---|---|--|
| Running time                              | Faster running time in most cases   | Will normally run longer but could run faster than Alt. 1                                  |
| Event Accuracy                            | Could neglect events which occur to other individuals during a given loop through the logic | Such events are not neglected since everyone is updated during each advance of the clock   |
| Capacity to handle cumulative interaction | Suppression only considers one man firing at one and neglects simultaneous firing           | Suppression includes the effect of many individuals firing at one (cumulative $P_K$ table) |

Figure 2.36. Comparison of Executive Alternatives

the clock, these types of events, which would tend to bias the results, could occur. With alternative two, such events are not neglected since the time of the first event for all individuals is first calculated and time is advanced in a fashion previously described. With respect to cumulative effects, alternative one neglects the fact that the suppression of an individual may be greater because three individuals may be firing at him rather than just one. Alternative two, on the other hand, can include these types of cumulative effects. As far as implementation goes, it is not clear that alternative one is superior to alternative two. Different logic is required for both alternatives, and a comparison is very difficult to make. Based upon the manner in which the reconnaissance model currently runs and an examination of these alternatives, alternative two was selected as the technique to be used for the SIAF combat model.

In summary, two executive routines are provided with the SIAF model. The first is the reconnaissance executive which operates in the manner described in Section 2.3. Once the detection and identification occurs the decision logic determines whether a combat action will occur. If a combat is to occur then the combat executive described above simulates this part of the mission. Once a combat mission is concluded and a decision is made to return to the reconnaissance operation, the reconnaissance executive routine described in Section 2.3 takes over and continues driving the model.

### 2.5.3 Data Structure and Manipulation

The SIAF combat model consists of a series of subroutines and an executive routine. The executive routine advances time in the manner previously described and calls individual subroutines to make various calculations. Interactions are considered and modeled by the subroutines which essentially update the attribute list of the target and SIAF shown in Figure 2.37. For example, ATT(1,1,1) is the fire team number of the first man in the attacker patrol. ATT(3,2,2) contains a value of the number of rounds remaining for man number 2 in the defender unit. The attribute matrix is a 25 x 20 x 2 matrix, and the attributes of each individual are changed by various subroutines depending upon the situation. For example, should movement occur then the current X and Y coordinates, attributes 7 and 8, of each individual involved in the movement are updated by the appropriate routine. Should a patrol member assume a different posture, then the height of the patrol member is

adjusted, attribute No. 11. Should his movement status change, for example, should he be in a suppression state where movement is not allowed, then the movement status attribute is changed. Attribute changes by one routine in turn effect other routines. For example, should the movement status change, the firing status would probably be different to allow the advancing unit to start moving again. Hence, the interactions between routines are essentially communicated to each of the routines through the attribute matrix. Naturally this is an oversimplification of the exact details of the model and is intended to be an overview to aid in understanding the details presented in Volumes V and VI.

#### 2.5.4 Calculation of Movement Event Times

As previously described in Section 2.5.2 five events are defined in the executive: movement times, detection times, casualty times, communication arrival times, and EFS burst event times. This section describes the calculation of movement event times. Figure 2.38 illustrates this calculation and shows the SIAF team in a line formation moving from one objective point to the next objective point which in this case is the point generated by a dynamic route subroutine. The model starts by computing the objective point for each individual based upon its formation of the unit. For a line formation the objective points would be as shown in the figure. If the formation were a "V" or a wedge then subroutine FORMST would compute the appropriate objective points for each individual and load these values into the ATT matrix. Specifically, these values would be located in ATT 9 and 10, the next movement coordinates. Next, based upon the present location of each individual, this subroutine calculates segment lengths for each individual. As shown in the figure, the segment lengths for each individual could be different and the path each individual takes could be over different terrain; hence, the movement rate model described previously in the reconnaissance section is called and the movement rate of each individual over each segment is calculated. Next these movement rates are modified by the current suppression state which is stored in the ATT matrix. Finally, the segment lengths are divided by movement rates to compute the time at which each individual would reach its next objective point. Then the minimum of all these times is calculated and stored in a variable called STIME.

(X) Next Dynamic Route Point

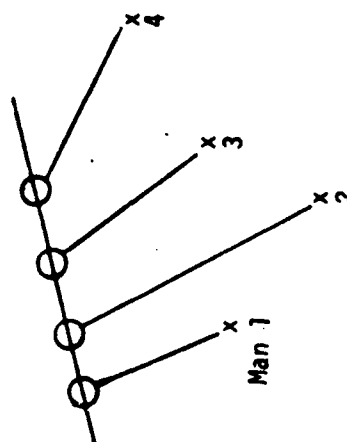

Figure 2.38, Calculation of Movement Event Times

### 2.5.5 Calculation of Detection Event Times

The previous section described how movement event times are calculated. In this section the calculation of detection event times is described and illustrated in Figure 2.39. First a specific SIAF and target individual are selected. Here detection times are based upon individual detections on individuals, that is, if there are 20 members in a SIAF patrol and 20 members in a target then there are 400 calculations made. After a SIAF individual and target individual are selected the terrain routines are entered and calculations made to determine if line-of-sight exists. If line-of-sight does not exist a no-detection verdict is entered. If line-of-sight does exist and the target is firing then the target is declared detected and time of detection is stored in the array DTIME as shown in the figure. Here the value of DTIME is the current time plus the reaction time which is the time it takes the individual to react to the detection and either change his posture, firing option, movement rate, or change another of his attributes based upon this detection. As shown in the figure, if line-of-sight exists but the target is not firing then a visual detection subroutine is entered to calculate the visual detection time TT. This routine is similar to the routine used in the reconnaissance model described in Volume III. Based upon this calculation the matrix DTIME is again loaded. Finally, the DTIME plus a maximum time are compared with the current time to allow for considering the fact that an individual might have detected another individual 5 seconds ago and the detection may still be valid. As shown in the figure the variable MDET is set equal to TRUE or FALSE which indicates whether the detection did or did not occur. The model proceeds in this fashion until all individuals in the SIAF patrol and all individuals in the target have been examined for detection.

### 2.5.6 Calculation of Casualty Event Times

Figure 2.40 describes this calculation which starts with computing the assigned area of responsibility of each individual. From this information the next calculation essentially determines a figure of merit and determines firing assignments which will maximize this figure of merit. Thus, this calculation determines the optimum strategy for the

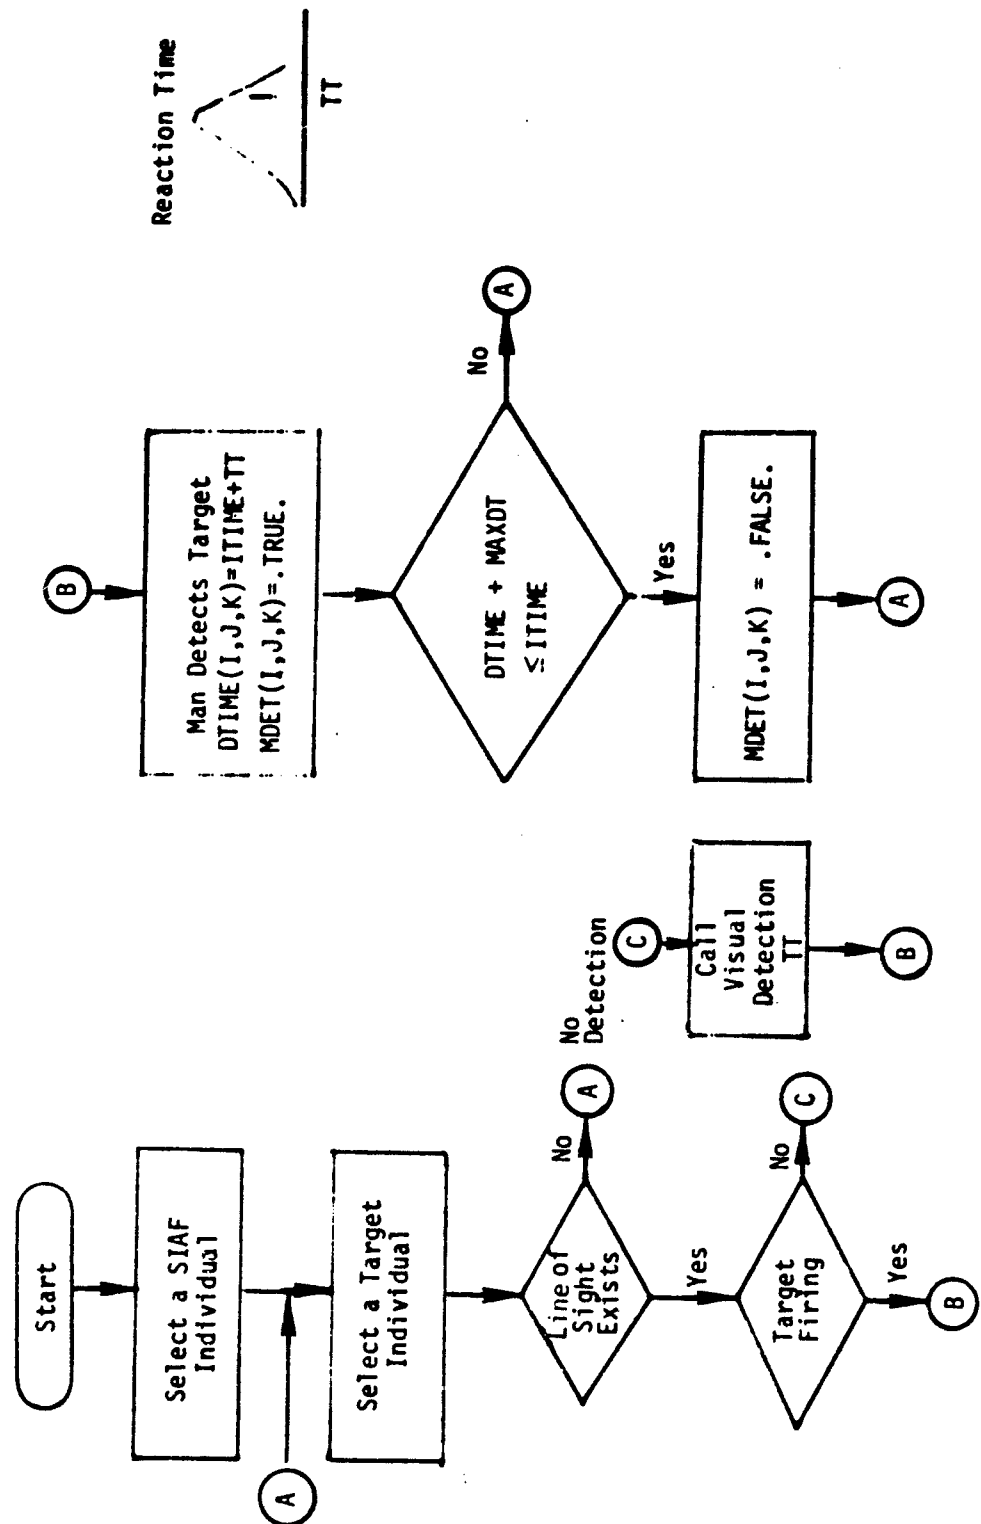

Figure 2.39, Calculation of Detection Events

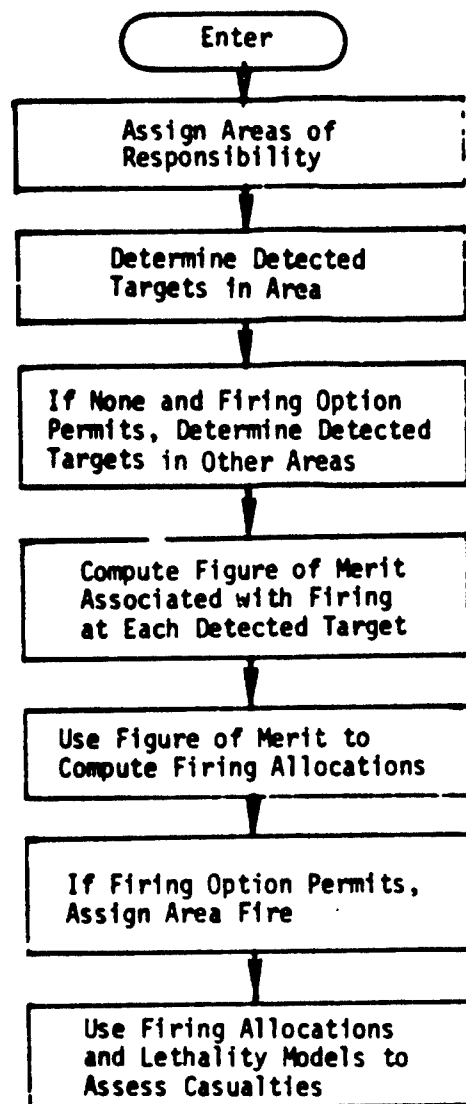

Figure 2.40, Calculation of Firing Events

target and SIAF patrol to use in firing. Based upon this optimum strategy, firing allocation and lethality models are entered to compute casualty times.

#### 2.5.7 Calculation of Internal Communication Event Times

One of the events considered is the reception of a communication from another maneuver unit within the patrol. This would occur after deployment when units are divided into moving maneuver units and a base of fire. In this case it may be necessary to communicate decisions such as break contact, change deployment points, or exchange roles between the moving units and the base of fire. The latter two would be in response to a reaction of the target such as a change in its route or deployment. Several options are available to provide communications. These are by visual hand signals, aural commands, radio, smoke grenades and by sending a messenger. For each type of message, the model has a preference order for attempting communication. These are dependent on the tactical situation. The internal communications routines, called by IC, determine whether or not the communication will be successfully received and interpreted, and they determine the delay time until the message can be implemented. The delay time becomes an event time because the result affects further progress of the combat, including firing, detection and movement status.

#### 2.5.8 Calculation of External Fire Support Event Times

The fifth event considered is an External Fire Support (EFS) event. This is defined as the arrival of a burst, either a volley of artillery or the weapons dropped in a single pass of a close air support aircraft. EFS is a scheduled event but its execution depends on the tactical situation. It is used preparatory to an attack mission. Upon identification of the target, the aimpoint is communicated and a schedule of arrivals is determined. If the target has not counterdetected the SIAF, then the arrivals are scheduled such that they are finished at the same time that the target reaches the minimum safe distance from the target. If this is the case, but the target subsequently counterdetects the SIAF, an immediate open fire command is sent and the schedule of arrivals is adjusted

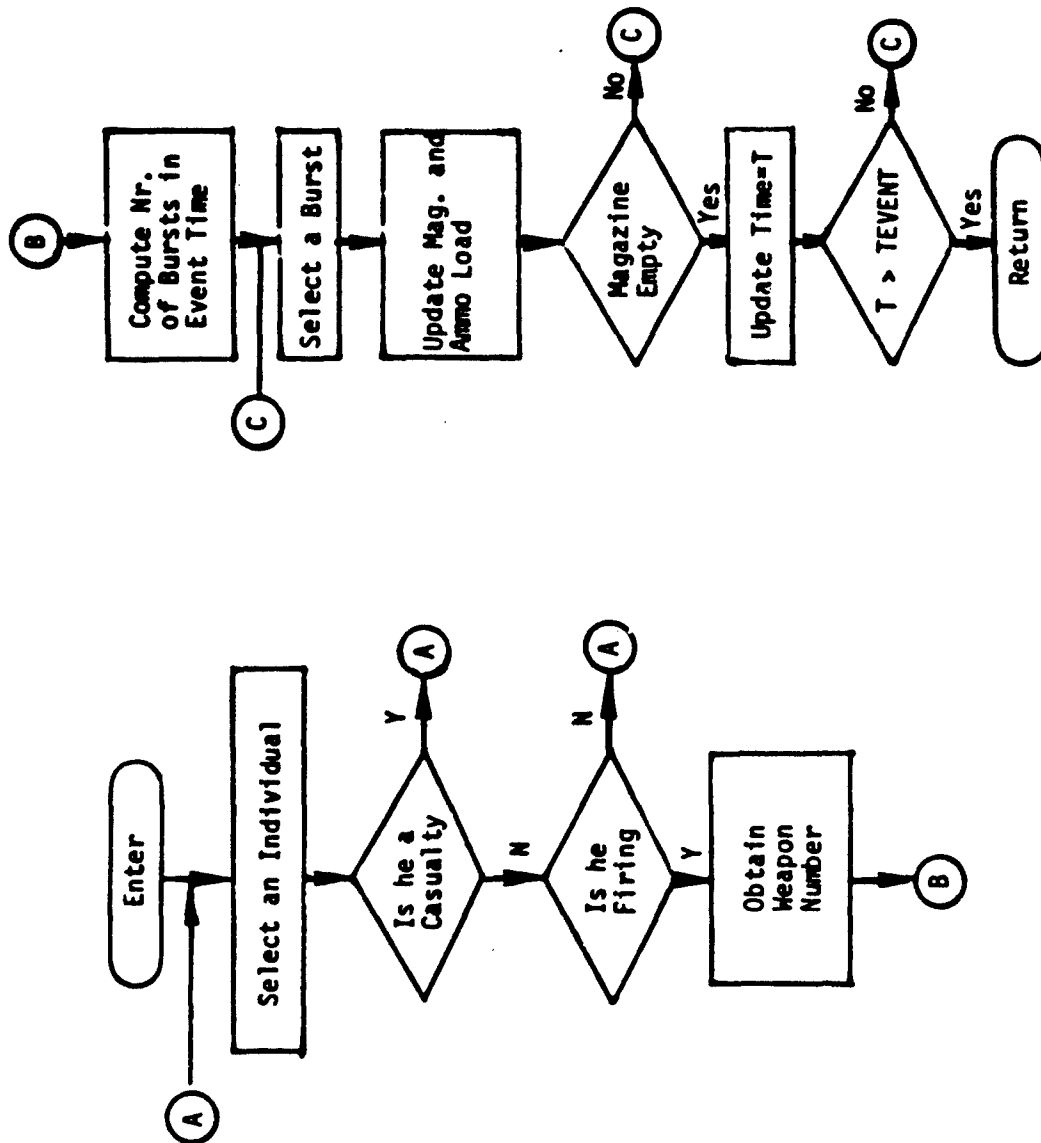

Figure 2.41, Ammunition Update Subroutine (AMMUP)

to start after a delay due to communications and time of flight. If the target has counterdetected the SIAF at the time of the original request, the delay time also includes time to make aiming calculations and to aim the weapons.

If external fire support is the next event, then Subroutine EFS1 is entered to compute the casualties due to each bomb or shell. This is done by considering aim point errors due to the inability of the SIAF to exactly determine the grid coordinates of the target. This includes both navigation errors and target location estimation errors. Also considered is the ballistic dispersion error. Once the aimpoint is determined (stochastically), the distance of each individual is determined and compared to the lethality data for the weapon. The attribute table is updated to account for any casualties.

Once these times are calculated the next event to occur be it movement, detection, casualty, EFS, or internal communication can be computed. If, for example, it is a movement event then the individuals are moved by updating the ATT matrix. If the next event is a detection event the corresponding logic is entered which will modify the movement rates and firing options based upon these detections. If, on the other hand, the next event was a casualty event then the appropriate element in the ATT matrix are updated to indicate that the individual has become a casualty. After these series of calculations are made the ammunition update, weapon substitution, break contact, and withdrawal routines are entered as appropriate. These routines are described in the next sections.

#### 2.5.9 Ammunition Update

The purpose of this subroutine is to update the ammunition of each individual based upon the current elapsed time and the firing scheme. This routine is described in Figure 2.41 which shows that the first calculation is to select an individual. Next, the question is asked, "is he a casualty?" If so, his ammunition is not updated since he could not have been firing. Hence, another individual is selected and the calculations proceed. If he is not a casualty and if he is firing then his weapon number is obtained from the ATT matrix and the number of bursts in the current event time are computed for this particular weapon and particular

SS<sub>BF</sub> = Suppression State for the Base of FireSS<sub>MU</sub> = Suppression State for the Maneuver Unit

firing rate of the individual. It could turn out that during the event time the magazine of the weapon became empty. Hence, the next series of calculations determines whether this occurred. If the magazine does become empty reloading time is entered into the calculation and modifies the number of rounds that the individual expended during the last event. If the magazine did not become empty, then number of rounds are computed based upon the event time and firing rate of the weapon. These calculations are done for each individual and the subroutine returns when all individuals have been examined.

#### 2.5.10 Weapon Substitution

If an individual becomes a casualty (major wound or death) in a particular event, it could turn out that the patrol operations plan is to have another individual take over his weapon. This normally occurs in a case of team weapons like grenade launchers, and machine guns. If the machine gunner is hit a patrol member who fires a rifle or grenade launcher will take over his weapon. An attempt to replace him with a rifleman is made first. If the man who is hit fires a grenade launcher an attempt is made to replace him with a rifleman only. Subroutine WSUBS provides the logic implementing this strategy. Figure 2.42 illustrates the calculations made. First, a unit is selected and here the assumption is that intra-unit weapon substitution is not allowed. That is, weapon substitution is only allowed within a particular unit. After a unit is selected the question is asked if the gunner who is a casualty fires a machine gun or a grenade launcher. If not, another unit is selected and this unit selection process continues until the number of units in a patrol and target are exhausted. If the patrol member under consideration is a casualty and is either a machine gunner or fires a grenade launcher and an appropriate replacement can be found then the ammunition of the replacement is updated, his weapon is switched and his next movement coordinates are changed. These calculations continue until all units have been examined for weapon substitution. (Note: If the user does not desire to play weapon substitution, this subroutine can be bypassed by appropriately adjusting the input variables. This is described further in Volume VI, Subroutine WSUBS.)

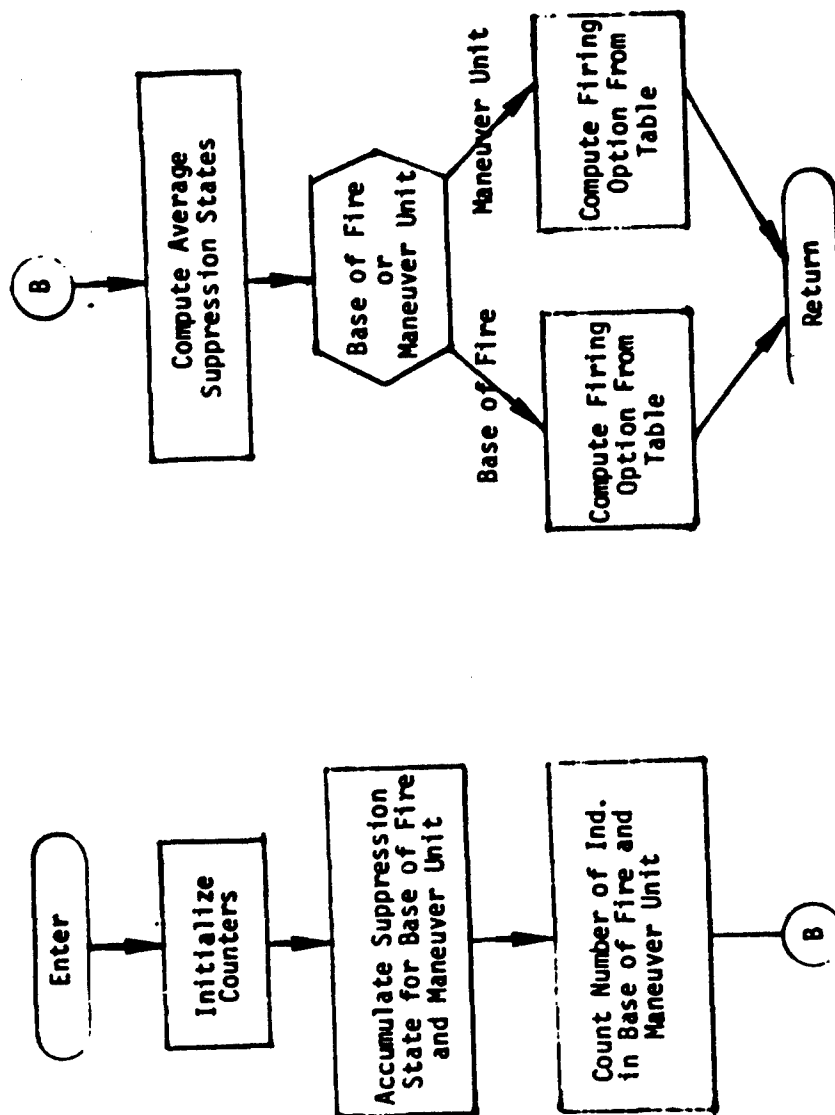

Figure 2.43. Firing Option Subroutine (FIREOP)

Table 2-3, Logic for Breaking Contact

| Break Variable        | Definition   | Criteria                              |
|-----------------------|--|---------------------------------------|
| Firepower             | $FP = \frac{\text{Firepower of Target}}{\text{Firepower of SIAF}}$ | Break if $FP > FP_{Max}$              |
| Casualty Fraction     | $CF = \frac{\text{SIAF Casualties}}{\text{SIAF Force Size}}$       | Break if $CF > CF_{Ma}$               |
| Time                  | $T = \text{Elapsed time of the firefight}$                         | Break if $T > T_{lim}$                |
| Loss of Key Personnel | $L_i = 1$ if the PL is hit<br>$L_i = 2$ if the PL and APL are hit  | Break if $L_i = j$ ( $j = 1$ or $2$ ) |
| SIAF - Target Range   | $R = \text{Minimum Distance Between SIAF and Target}$              | Break if $R < R_{lim}$                |
| Ammunition            | $A = \text{Average Number of Rounds Remaining (per troop)}$        | Break if $A < A_{lim}$                |

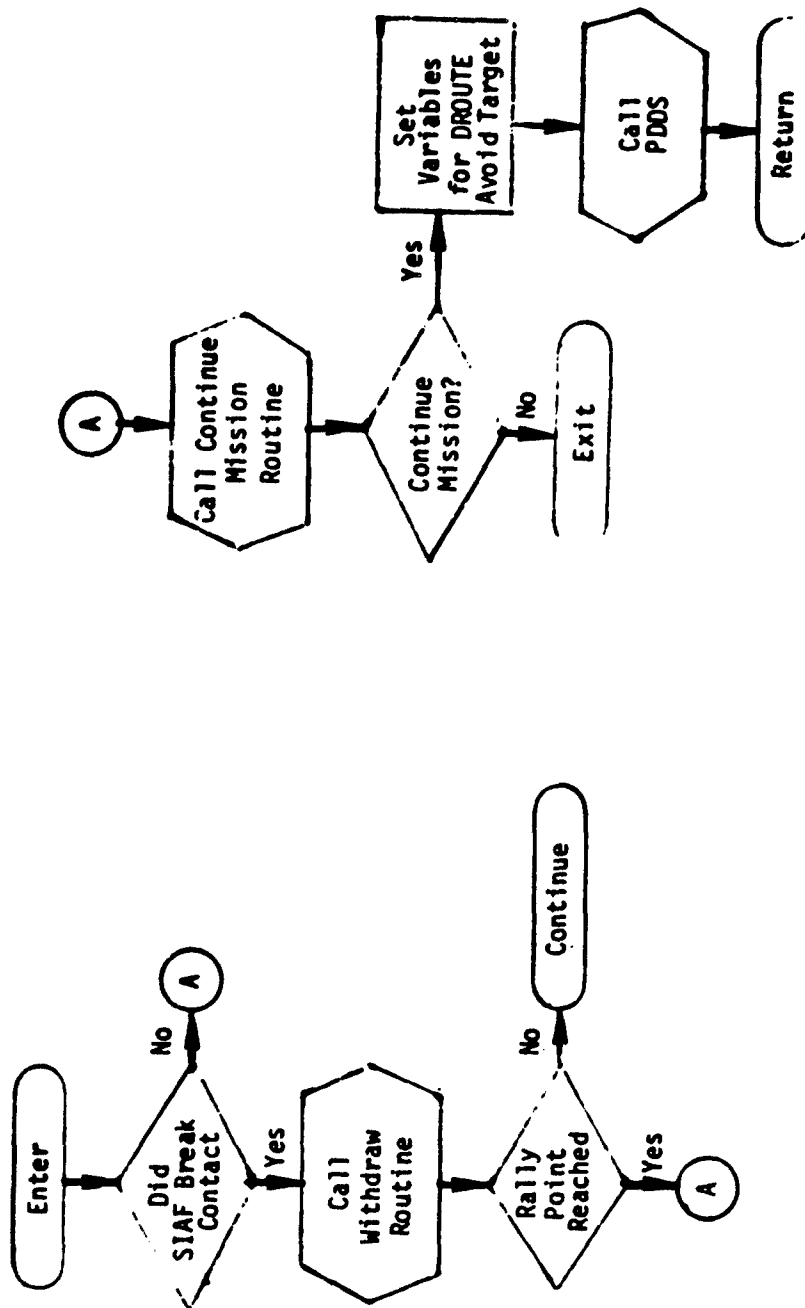

Figure 2.44, Logic For Continuing Reconnaissance After Combat

### 2.5.11 Firing Options

This particular section describes and presents an overview of how firing options are changed dynamically throughout the conduct of the simulation. Table 2-1 shows the firing options considered in the model. For example, Firing Option 0 is simply "don't fire". Firing Option 1 says, "fire if targets are in your area of responsibility. If none, then don't fire". Option 2 says "fire if detected targets are in area of responsibility. If none, then conduct area fire in area of responsibility." Options 3 and 4 are similar and can be examined by studying Table 2-1. Table 2-2 shows the firing options of both the base of fire and maneuver unit and here the numbers correspond to the options previously described in Table 2-1. For the base of fire, the firing option is a function of their own suppression state and the suppression state of the maneuver unit since their mission is to support the advance of the maneuver unit. The firing options of the maneuver unit on the other hand is a function of their own suppression state only. As an example, Table 2-2 shows that if the maneuver unit in suppression state 0 through 3 their firing option is 0, that is "don't fire". If they are in suppression state 4, 5, or 6, however, their firing option is firing option 2 which states fire at detected targets in area of responsibility. Hence, the firing options can be changed for the base of fire and the maneuver unit by user input data depending upon which particular strategy the user wishes to simulate.

Figure 2.43 shows how this logic is implemented in subroutine FIREOP. When the subroutine is entered counters are initialized and the suppression state for all individuals in the base of fire and maneuver unit is accumulated. Next the number of individuals in the base of fire and maneuver units are counted and the average suppression state of each of these units is computed. Table 2-2 is entered and the appropriate firing option computed by means of table look-up. In this fashion the firing options of both the base of fire and maneuver unit are dynamically adjusted throughout the execution of the combat mission.

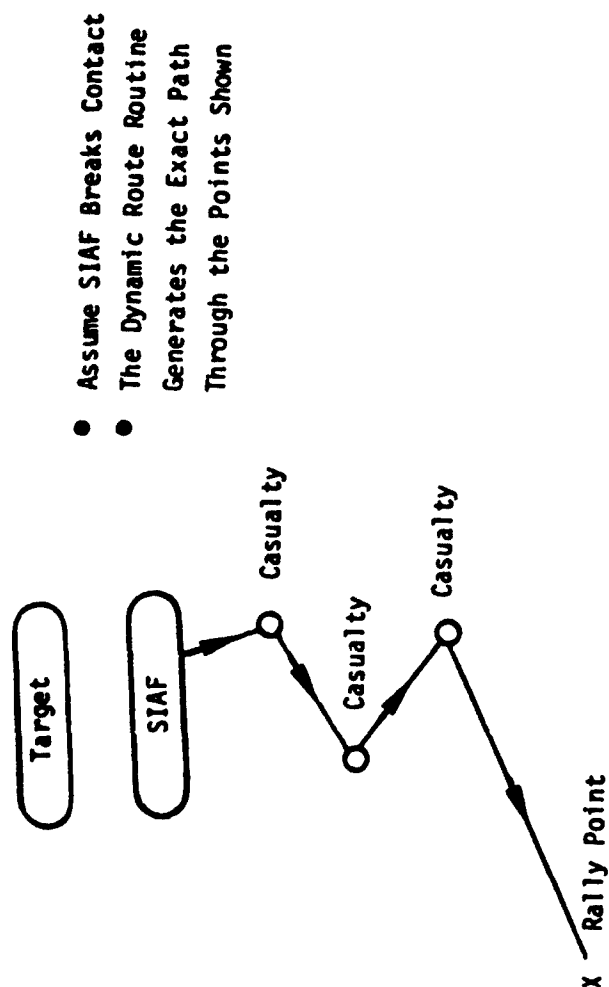

Figure 2.45, Illustration of Withdrawal Model

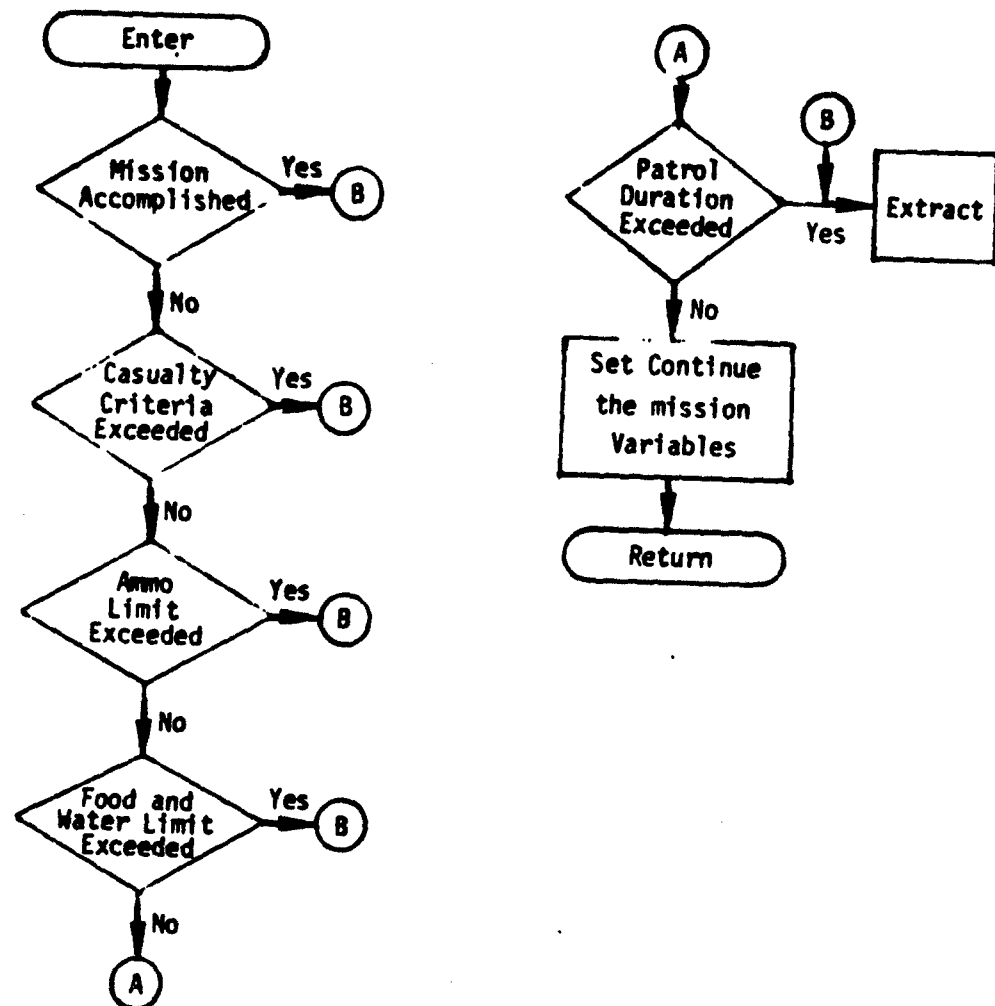

Figure 2.46, Continue The Mission Subroutine

This firer also has the option of firing his normally assigned weapon or throwing a handgrenade. Dependent upon the figure of merit calculated for both his normally assigned weapon and a handgrenade, for the situation that the firer under consideration is in, a decision is made as to which weapon to utilize. The handgrenade is basically used at short ranges under high suppression.

#### 2.5.12 Mines

A SIAF patrol has the capability of Claymore mine ambush. Figure 2.46A depicts a typical mine field deployment. The user specifies a Claymore mine ambush intent by inputting the required inputs, and upon the enemy patrol reaching the most lethal point in the field (middlemost) the mines are detonated. The cumulative probability of kill of all mines in the field upon each target element is computed and the cumulative probability is Monte Carloed for each target individually to determine if the target suffered a minor wound (hit), major wound, or death. Figure 2-46-B shows how this logic is implemented in Subroutine MINES.

#### 2.5.13 Break Contract

In each loop of the simulation, logic for breaking contact is entered if a break contact event is to occur and if so, a determination is made as to which side breaks contact. The break variables described in Table 2-3 are fire power, casualty fraction, time, loss of key personnel, SIAF-target range and ammunition. The criteria for breaking contact are adjusted by means of user input for both the SIAF patrol and for the target. For example, if the user wishes to implement a strategy whereby the SIAF patrol breaks contact after their ammunition reaches 30% of the initial load they implement this strategy by appropriately adjusting the ammunition limit variable shown in the table. The other criteria shown in the table are used in a similar manner. The break contact logic implements a break contact decision if any of the criteria are satisfied.

#### 2.5.14 Withdraw

Figures 2.44 through 2.46 describe how we model a situation where SIAF returns to its reconnaissance mission after the combat operation has been completed. As seen from Figure 2.44, this routine is entered once the proper break contact variable has been set. The first question asked

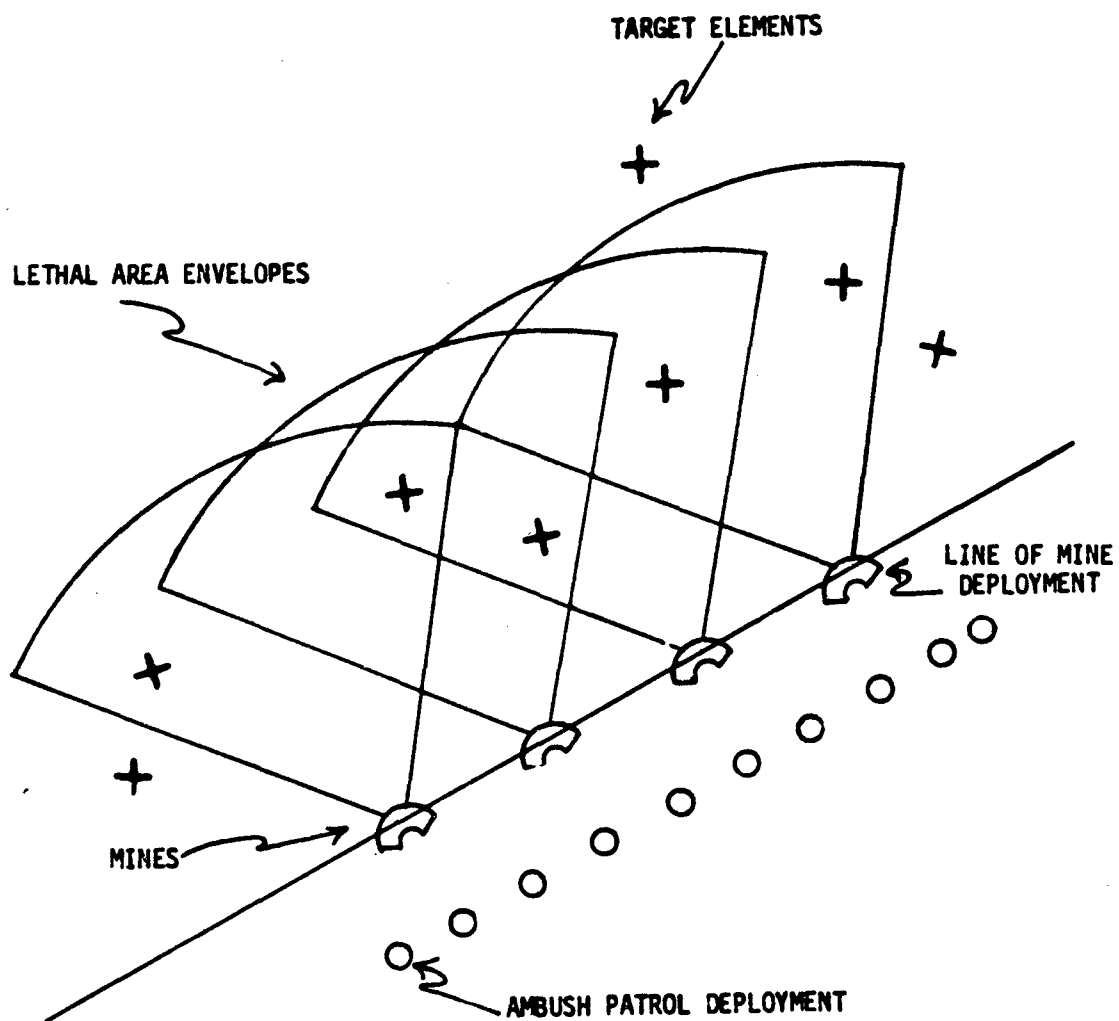

Figure 2.46A Typical Minefield Deployment

USER INPUT:

NUMBER OF MINES  
LENGTH OF FIELD  
ANGLE OF DEPLOYMENT  
CENTER OF FIELD

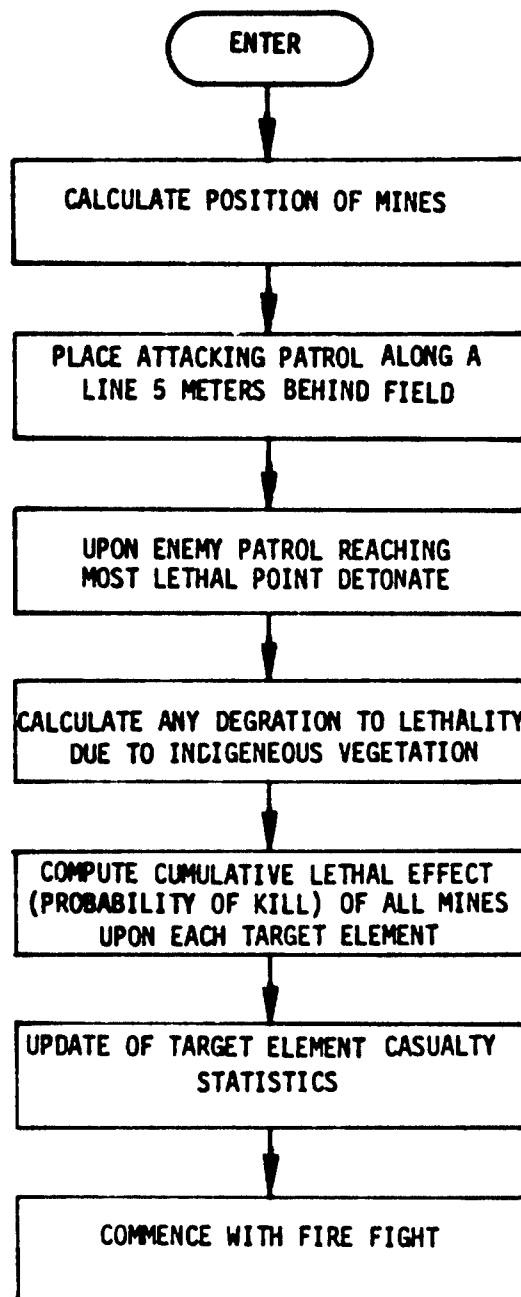

Figure 2.46B, Logic Diagram (MINES)

is, "did SIAF break contact?". If not, then no withdrawal is required for the SIAF unit and the continue-the-mission subroutine described in Figure 2-46 is entered. If SIAF did decide to break contact, then a withdrawal routine is entered. This withdrawal routine calculates the major withdrawal objective points for the patrol. Next, the withdrawal is simulated until the rally point is reached. Once the rally point is reached, the continue-the-mission decision subroutine is entered and if the decision is to continue the mission, then dynamic route variables are set up to avoid the target and get the patrol back to the planned route.

Figure 2.45 illustrates the withdrawal model which forces the patrol to pass through points where a casualty has occurred to the rally point. As indicated in Figure 2.45 the dynamic route subroutine is called to generate the exact route through the casualty locations to the rally point.

#### 2.5.15 Continue the Mission

Once the rally point is reached, the continue-the-mission subroutine shown in Figure 2.46 simulates the patrol leader's decision to extract or go back to the planned route. This decision is based upon the variables shown which are mission objective, casualty criteria, ammunition limits, food and water limits, and patrol duration limits. By adjusting these limits which are user input values, the user can select the criteria he wishes to use in simulating the decision to continue the mission or extract. If a continue-the-mission decision is reached, dynamic route variables are set and subroutine PDDS (see Volume III) is called to generate the route back to the planned path. If the decision is to extract then the model terminates and variables are initiated for the next replication.

#### 2.5.16 Summary of Attacker and Defender Options

Prior to a detection occurring, the SIAF Reconnaissance Model simulates the SIAF mission as discussed in Section 2.4. Once a detection and identification is made (either by SIAF or by the target), the party making the detection and identification becomes the attacker and the other party becomes the defender.

As discussed in Section 2.5.1, the attacker will select one of five options, viz, 1) EES only, 2) ambush, 3) move with stealth to attack, 4) deploy for ambush with mines, 5) no combat. Meanwhile, the defender, having not yet detected, continues to move along his preplanned route. If the attacker selects options 2 or 3, a deployment point is computed and the dynamic route routine generates the attacker's route between his present position and the deployment point. If the defender detects the attacker before the attacker initiates the firefight, then the defender initiates the firefight or selects an alternative course of action to protect its position.

Once the firefight commences, the defender remains stationary unless he decides to break contact. If the target decides to break contact, the engagement is considered complete and SIAF decides whether to continue its mission. However, if SIAF decides to break contact, the withdrawal is simulated until the rally point is reached, at which point SIAF decides whether to continue its mission, in which case the SIAF Reconnaissance Model is again employed to simulate the remainder of the mission.

#### 2.5.17 Summary of Model Capacities

This section summarizes the current capacities of the model. A summary of computer requirements is given in Sections 7.1 and 7.2 of this volume.

- Maximum number of men on each side = 20
- Maximum number of different weapons = 20
- Maximum number of different grenade launches = 10
- Maximum grid of terrain elevation points = 1366
- Maximum number of targets = 20
- Maximum number of preplanned route points for each target = 20
- Maximum number of preplanned SIAF route points = 100
- Maximum number of helicopter landing points = 5
- Maximum number of weather changes = 100
- Maximum length of simulated patrol = 10 days

### 3.0 MODEL INPUT

The model input data consists of users inputs, data base, and elevation data. The elevation data is taken directly from digital TOPOCOM tapes from the Defense Mapping Agency. When a particular area of operations is desired, a set of subroutines is used to generate a file of elevation data which can be permanently stored. This file can then be accessed at the start of each run as long as the area of operations remains the same. This file contains elevation data at the maximum resolution (or minimum separation). The model then reads from this file to obtain data for the required resolution. The maximum elevation points at any one time is 8196.

The remaining data inputs are read via NAMELIST card input. In general, the namelist card input has been organized into categories of data base (NAML1), user input (NAML2), target oriented user inputs, (NAML3), and combat oriented user inputs (NAML4). Table 3.1 contains a complete list and definition of all of the required input variables. This table is organized by first presenting user inputs, (those variables specific to a situation) and then presenting the data base. (Variables whose values are unlikely to change from run to run). Within these categories the data is organized by categories according to the use of the variables. For example, all of the required inputs to describe the targets are found together.

The variables in the data base are further described by default values which are current best estimates. These need only be changed if better data become available.

Table 3.2 contains a cross reference to Table 3.1. Here all variables from the namelists are presented in alphabetical order with the sheet number of the corresponding location in Table 3.1. It is felt that this method of presentation allows the user to better understand the meaning of a variable because he is able to see its definition in the context of other variables with which it is associated.

**USER INPUT****SET UP**

JSTART Starting point within run if RESTRT feature is used (See Volume III, Section 10.4)

JSTOP Termination point within run if STOP feature is to be used for later RESTRT.

NCOPY Number of copies of summary output desired

MICR1

Linear obstacle type; for L=1,2,3,...,NOB where IOB(L) =

IOB(L)

- 1 if linear obstacle L is a river
- 2 if linear obstacle L is a stream
- 3 if linear obstacle L is a ravine
- 4 if linear obstacle L is a dike
- 5 if linear obstacle L is a canal
- 6 if linear obstacle L is a cliff
- 7 if linear obstacle L is a road
- 8 if linear obstacle L is a trail
- 9 if linear obstacle L is a lake or reservoir

ITRC(L)

Geometry of L<sup>th</sup> polygon, where  
1 if L<sup>th</sup> polygon is a triangle  
2 if L<sup>th</sup> polygon is a rectangle  
3 if L<sup>th</sup> polygon is a circle  
for L=1,2,3,..., NRVP+NRMP+NRSOIL

(XOB(I,L);  
YOB(I,L))

Coordinates of start point of segment I of obstacle L, for L=1,2,...,NOB, and I=1,2,... (NCO(L)+1) or coordinates describing the geometry of the L<sup>th</sup> polygon

NCO(L)

Number of line segments comprising linear obstacle L, for L=1,2,3,...,NOB

ICL(L)

Class of the L<sup>th</sup> polygon, for L=1,2,...,NRVP+NRMP+NRSOIL

Table 3-1, Namelist Inputs (Sheet 3)

### NAVIGATION DEVICES

**PPLS** Portable Position Location System. If such a device is carried by SIAF, PPLS=1, if not carried by SIAF, set PPLS=0.

**TBUR** Set TBUR=0 if it is impracticable to use PPLS or if sufficient time is not available. TBUR=1 if sufficient time is available only for a "quick" navigation fix. (2 min. after aircraft arrival, CEP=150.) TBUR=2 if sufficient time (15 min.) is available for an accurate navigational fix (CEP=60 meters).

**Map Scale**

**SPECIAL CASE.** Allows override of HumRRO SIAF navigation specs. Input revised limit on standard deviation of distance between actual SIAF location and believed SIAF location. (HumRRO nav. specs. are used if SPEC is input as zero.)

**SCALE**

**SPEC**

## SIAF INPUTS

DESCRIPTION

|       |   |          |
|-------|---|----------|
| SC(1) | Average height of a SIAF element              | - meters |
| SC(2) | Average width of a SIAF element               | - meters |
| SC(4) | Number of men in the SIAF patrol              |          |
| SC(5) | Average visual reflectivity of a SIAF element |          |
| SC(6) | Hearing threshold for a SIAF member           | - dB     |

{ 0 if a vegetation class dependent formation is to be used for SIAF  
 1 if specific formation number 1 is to be used for SIAF  
 2 if specific formation number 2 is to be used for SIAF  
 5 if specific formation number 5 is to be used for SIAF

|                      |   |
|----------------------|---|
| ISTAY(IP,IZ)         | $\left\{ \begin{array}{l} 0 \text{ if route checkpoint IP for insertion} \\ \text{point IZ is not a non-movement point} \\ 1 \text{ if route checkpoint IP for insertion} \\ \text{point IZ is a non-movement point} \end{array} \right.$ |
| ITMOV(IP,IZ)         | Planned departure time from checkpoint IP<br>for insertion point IZ. - days, hrs, min, sec.   |
| <u>TARGET INPUTS</u> |   |
| NTAR                 | Total number of targets   |
| NFIX                 | Number of targets located specifically by user.<br>(Others located randomly)  |
| ITST(IT)             | Time when target IT is created in the model. - days, hrs, min, sec.   |
| ITSTOP(IT)           | Time when target IT is eliminated from the<br>model. - days, hrs, min, sec.   |
| IDET(IT)             | $\left\{ \begin{array}{l} 1 \text{ if target IT is to be considered on an} \\ \text{element-to-element basis} \\ 0 \text{ otherwise} \end{array} \right.$   |
| <u>MOVEMENT</u>      |   |
| IMV(IT)              | $\left\{ \begin{array}{l} 1 \text{ target IT is fixed} \\ 2 \text{ target IT moves at random} \\ 3 \text{ target IT moves according to a time} \\ \text{and checkpoint plan} \end{array} \right.$   |

Table 3-1. Namelist Inputs (Sheet 8)

## TARGET INPUTS (Continued)

## Movement (Cont'd.)

For IMV = 2 or 3 supply =

|             |   |
|-------------|---|
| FRCMVD(IT)  | Fraction of the time target IT is moving during the day                           |
| FRCMVN(IT)  | Fraction of the time target IT is moving during the night                         |
| RAINMAX(IT) | Maximum range target IT can travel. (Random only) - meters                        |
| TVEL(IT)    | Velocity of the IT <sup>th</sup> target. (0 if not a manned target) - meters/sec. |

IF IMV = 3 also add

|               |  |                              |
|---------------|--|------------------------------|
| IMP(IT)       | Number of movement periods for target IT.                                    |                              |
| ITIMS(IL,IT)  | The time that target IT initiates movement - days, hrs, min, sec. period IL. |                              |
| GOALTX(IL,IT) | The X coordinate of the goal point for movement period IL of target IT.      | 4-digit military coordinates |
| GOALTY(IL,IT) | The Y coordinate of the goal point for movement period IL of target IT.      | 4-digit military coordinates |
| TC(1,IT)      | The X starting coordinate for the IT <sup>th</sup> target (0 if random).     |                              |
| TC(2,IT)      | The Y starting coordinate for the IT <sup>th</sup> target (0 if random).     |                              |

Table 3-1, Jamelist Inputs (Sheet 9)

For Reconnaissance  
(See DETECT)

TARGET INPUTS (Continued)

|               | <u>CHARACTERISTICS</u>  |          |
|---------------|---|----------|
| TC(3.IT)      | The average height of an element of target IT.  | - meters |
| TC(4.IT)      | The average width of an element of target IT.   | - meters |
| TC(5.IT)      | The number of fire teams making up target IT.   |          |
| TC(6.IT)      | The number of elements making up target IT.   |          |
| TC(7.IT)      | The average visual reflectivity of an element of target IT.   |          |
| TC(8. IT)     | The average 1.06 micron reflectivity of an element of target IT (for laser designation).  |          |
| TC(9.IT)      | The hearing threshold for a member of target IT.  | - dB     |
| IFT(IT)       | <u>FORMATION</u><br>{ 0 if a vegetation class dependent formation is to be used<br>{ 1 if a specific formation for target IT is to be used (e.g., a fixed set of buildings)<br>}<br>The locations within a target for a special formation of each of the J elements for target IT |          |
| FORMT(I,J.IT) |   |          |

Table 3-1, Hamelist Inputs (Sheet 10)

For Reconnaissance  
(See UTECT)

TARGET INPUTS (Continued)  
Formation (Cont'd)

Where:  $I = 1$  is the X location of element J relative to the  $J = 1$  element  
 $I = 2$  is the Y location of element J relative to the  $J = 1$  element  
 (only used if  $IFT(IT) = 1$ )

SOUND TRACK

|               |  |                        |
|---------------|--|------------------------|
| NSTP(IT)      | Number of special sound track periods of target IT                       |                        |
| ISSOFF(IK,IT) | The time when the $IK^{th}$ sound period stops operating for target IT   | - days, hrs, min, sec. |
| ISSON(IK,IT)  | The time when the $IK^{th}$ sound period starts to operate for target IT | - days, hrs, min, sec. |
| SOUNDT(IK,IT) | Sound level for $IK^{th}$ sound period for target IT.                    | - dB                   |

Table 3-1. Jamelist Inputs (Sheet 11)

## TARGET INPUTS (Continued)

DETECTION

RCMAX(IT)

The range between a target IT and SIAF which describes the distance beyond which detailed detection computations are not desired.

- meters

RCMIN(IT)

The range between a target IT and SIAF that always requires detailed detection computations without first checking feasibility.

- meters

(See TARGET)

POST DETECTION

0 if target IT is to be eliminated upon detection

1 if SIAF should proceed toward target IT in order to identify the target given that it cannot be identified at detection

2 if SIAF should call external fire support against target IT after advancing for identification

3 if SIAF should avoid target IT upon first detection of target IT.

(See PDDS)

KREG(IT)

Table 3-1, Namelist Inputs (Sheet 12)

| TARGET INPUTS (Continued) | EXTERNAL FIRE SUPPORT<br>(This Section For EFS<br>Only Attack)  |
|---------------------------|---|
| IFSUP(IT)                 | { 0 no external fire support available<br>{ 1 artillery support available - Also used for combat<br>{ 2 air support available |
| IFADJ(IT)                 | <u>Artillery</u><br>{ 0 if fire without adjustment<br>{ 1 if fire with adjustment   |
| ITACT(IT)                 | { 1 if target digs in in-place<br>{ 2 if target expands circularly (if IFADJ(IT) = 1)<br>{ 3 if target moves to cover         |
| IANG(IT)                  | <u>Close Air Support</u><br>{ 1 if air/ground machine guns are used<br>{ 0 if air/ground machine guns are not used            |
| ICBOM(IT)                 | { 1 if cluster bombs are used<br>{ 0 if CBU's are not used  |
| IGBOM(IT)                 | { 1 if general purpose bombs are used<br>{ 0 if general purpose bombs are not used  |
| IFAR(IT)                  | { 1 if folding fin A/C rockets are used<br>{ 0 if FFAR's are not used   |

Table 3-1, Namelist Inputs (Sheet 13)

## TARGET INPUTS (Continued)

|           |  |                 |
|-----------|--|-----------------|
|           | <u>If Using Cluster Bombs</u>  |                 |
| FMCB1(IT) | Lethal area of CBU bomblet versus first pass personnel posture                 | - square        |
| FMCB2(IT) | Lethal area of CBU bomblet versus second and subsequent pass personnel posture | - square        |
| NCB(IT)   | Number of ordnance delivering passes, CBU                                      |                 |
|           | <u>If Using General Purpose Bombs</u>  |                 |
| FMGPB(IT) | Mean area effectiveness (GP) - personnel posture                               |                 |
|           | <u>If Using Rockets</u>  |                 |
| FMA1(IT)  | Lethal area of rockets versus second and subsequent passes personnel posture   | - square meters |
| FMA2(IT)  | Lethal area of rockets versus second and subsequent passes personnel posture   | - square meters |
|           | <u>If Using Machine Guns</u>   |                 |
| NGF(IT)   | Number of rounds of machine gun fire   |                 |
| VAX(IT)   | Personnel vulnerable area to MG projectiles.                                   | - square meters |

Table 3-1. Namelist Inputs (Sheet 14)

WEATHER INFORMATION

|           |  |                     |
|-----------|--|---------------------|
| TSR       | Time of sunrise                                | days, hrs, min, sec |
| TSS       | Time of sunset                                 | days, hrs, min, sec |
| NWCL(I,1) | Time at which weather class changes            | days, hrs, min, sec |
| NWCL(I,2) | New weather class commencing at time NWCL(I,1) | -                   |
| WDAY(I,J) | Daily weather information                      |                     |
|           | I: Day of the patrol.                          |                     |
|           | J: 1 = time of moonrise                        | hrs, min            |
|           | 2 = time of moonset                            | hrs, min            |
|           | 3 = type of moon                               |                     |
|           | Type 0 = New Moon                              |                     |
|           | Type 1 = 1/4 Moon                              |                     |
|           | Type 2 = 1/2 Moon                              |                     |
|           | Type 3 = Full moon                             |                     |
|           | 4 = Maximum temperature                        | °F                  |
|           | 5 = Minimum temperature                        | °F                  |
|           | 6 = Maximum relative humidity                  | %                   |
|           | 7 = Minimum relative humidity                  | %                   |
|           | 8 = Minimum wind velocity                      | kts                 |
|           | 9 = Average wind velocity                      | kts                 |
|           | 10 = Maximum wind velocity                     | kts                 |
|           | 11 = Direction wind is coming from             | Compass bearing     |
|           |  | 0 - 360°            |

Table 3-1, Namelist Inputs (Sheet 15)

COMBAT INPUTSHUMAN

|              |  |                |
|--------------|--|----------------|
| XMU          | Mean human reaction time to detection  | Seconds        |
| SSIG         | Standard deviation of human reaction time to detections  | Seconds        |
| UNKCON       | Factor to compute area of uncertainty of target position as a function of the elapsed time since the target was last seen.       |                |
| VELNOM (I,K) | Nominal velocity, moving normally $I = 1$ , or moving at top speed $I = 2$ , where $K = 1$ for attackers, $K = 2$ for defenders. | Meters/Seconds |
| FHCR         | Fraction of height below which subject is said to be not standing  |                |
| FHPR         | Fraction of height below which subject is said to be prone.  |                |
| XMAXDT       | Elapsed time from last detection after which target position becomes unknown.  | Seconds        |
| MAXDT        | Maximum time after which previous detections lose their value  | Seconds        |

FIRING

|           |   |         |
|-----------|---|---------|
| DELTA     | Increment by which firing allocations are varied in the point fire allocation model (See FALØC) |         |
| AIMMX (K) | Contains maximum aiming time; $K = 1$ attacker, $K = 2$ defender                                | Seconds |
| FTAPB (K) | Contains fraction of time between bursts spent aiming; $K = 1$ attacker, $K = 2$ defender       | Seconds |
| DTEFS     | Maximum probable delay of EFS after EFS is called   | Seconds |
| HFR       | Height above terrain cutoff for firing  | Meters  |

Table 3-1, Namelist Inputs (Sheet 16)

| Firing (Cont'd) | Firing rate degradation factor when the fraction of ammunition remaining is of index I; J = 1 for point-fire weapons, J = 2 for area-fire weapons  | <u>FORMATIONS</u> (For Combat Only; See FORMST) | Meters |
|-----------------|--|---|--------|
| DF(I,J)         |  |   |        |
| IPERM(J,M)      | Contains the positions of a fire team. J indicates the fire team number and M indicates the particular permutation of fire team positions within their maneuver unit. (M = 1, 2, 3, 4, or 5).  |   |        |
| IFORFT (J)      | The formation type to be used by the individual within a fire team. Examples: = 1 column, = 2 wedge, = 3 vee, = 5 echelon right, = 6 echelon left; where J, = 1 for stealth, J = 2 for fire and movement, J = 3 for assault, J = 4 for pursuit, J = 5 for withdrawal, J = 6 for stopped. |   |        |
| IFORMT(J)       | The formation type for fire teams within maneuver units (same as for IFORFT).  |   |        |
| FORFTX (K,J)    | The relative X location of the Kth position within fire team formation J   |   |        |
| FORFTY (K,J)    | The relative Y location of the Kth position within fire team formation J   |   |        |
| FORMUX(I,J)     | The relative X location of the Ith fire team in maneuver unit formation J  |   |        |
| FORMUY(I,J)     | The relative Y location of the Ith fire team in maneuver unit formation J  |   |        |
| FORSFX(J)       | The relative spacing in the X direction of the patrol element from the fire team leader of fire team formation type J  |   |        |

Table 3-1, Namelist Inputs (Sheet 17)

| Formations (Cont'd) |   | <u>FIRING ALLOCATION</u>  | Meters |
|---------------------|---|---|--------|
| FORSFY(J)           | The relative spacing in the Y direction of the patrol element from the fire team leader of fire team formation type J         | Contains minimum fraction of fire power directed against each detected target; K = 1 defender, K - 2 attacker   |        |
| FORSMX(J)           | The relative spacing in the X direction of the fire team in position from the leader of the maneuver unit in formation        | Contains weapon weighting factor for firing allocation  |        |
| FORSWY(J)           | The relative spacing in the Y direction of the fire team in position from the leader of the maneuver unit in formation type J | J = 1 - attacker applies to defender's weapons<br>2 - defender applies to attacker's weapons  |        |
| COLMIN(K)           |   | I = 1 - simi-automatic weapon<br>2 - automatic weapon<br>3 - grenade launcher   |        |
| WPWT(I,J)           |   | Contains minimum length of each man's area of responsibility;<br>K = 1 attacker, K - 2 defender   |        |
| ARSMN(K)            |   | Contains fractional overlap of each man's area of responsibility;<br>1 attacker, 2 defender   |        |
| ARSPI(K)            |   |   |        |
| FDGFAC(K)           |   | Contains lateral distance on each side of right-most and left-most targets for defending total area of responsibility; K = 1 defender, K - 2 attacker |        |

Table 3-1, NameList Inputs (Sheet 18)

DEPLOYMENT CRITERIA (See DLOGIC)

|           |   |                              |
|-----------|---|------------------------------|
| RAMB      | Ambush range between deployment point and engagement point  | Meters                       |
| RAWIN     | Minimum admissible value of RA (see subroutine DLOG5)   | Meters                       |
| RATT      | Attack range between deployment point and engagement point  | Meters                       |
| REFS      | Minimum admissible distance between the subject patrol and object patrol for calling EFS.   | Meters                       |
| ROBS      | Maximum admissible distance between the subject patrol and the engagement point to use detailed terrain information (See DLOG7)               | Meters                       |
| RSP       | Approximate distance desired between trial deployment points  | Meters                       |
| RZ        | Maximum admissible ratio of line-of-sight cut-off distance to range to observed target for adequate cover due to line-of-sight obstruction    |                              |
| IOIREC    | 1 - SIAF to be the subject patrol<br>2 - target to be the subject patrol  | In case of<br>standoff only. |
| IPURSU(J) | = 0 if the maneuver unit is not to pursue the defender in the withdrawal mode past the last attacker objective point (presently not used).    |                              |
| GSAPRR    | Approximate spacing desired between rows and between columns of predeployment movement area array. (See DLOG8)                                | Meters                       |
| NSECT     | Number of angular increments (through pi radians) subtended by the circular array of trial deployment points about a stationary object patrol |                              |

Table 3-1, Namelist Inputs (Sheet 19)

| Deployment Criteria (Cont'd) |  |         |
|------------------------------|--|---------|
| CADM                         | Minimum admissible value of ADM, where ADM is the average merit value of trial points set in predeployment movement area ( $0 \leq \text{CADM} \leq 1$ ). (See DLOGIC) |         |
| FRAMB                        | Minimum admissible force ratio for ambush  | Seconds |
| FRATT                        | Minimum admissible force ratio for attack  | Seconds |
| GMAX                         | Maximum admissible slope from deployment point to engagement point for engagement  | Seconds |
| CC1                          | Percentage thresholds, to be used jointly, with PP1, . . . , PP5, for determining adequate cover, concealment, and observation (see subroutine CCO).                   |         |
| CC2                          |  |         |
| CC3                          |  |         |
| CLASS(J,K)                   | 0 if micro-relief Class J and vegetation Class K are deemed jointly admissible for a deployment point (See DLOG7).   |         |
|                              | 1 if micro-relief Class J and vegetation Class K are deemed joint conditionally admissible   |         |
|                              | 2 if micro-relief Class J and vegetation Class K are deemed joint inadmissible   |         |
| DTDAMB                       | Minimum deployment time required for ambush  | Seconds |
| DTDATT                       | Minimum deployment time required for attack  | Seconds |
| DTENGM                       | Maximum admissible time for object patrol to move to engagement point  | Seconds |
| DTPURM                       | Maximum admissible time for subject patrol to move to deployment point.  | Seconds |

Table 3-1. Hamelist Inputs (Sheet 20)

## Deployment Criteria (Cont'd)

PP1  
PP2  
PP3  
PP4  
PP5

Probability thresholds, to be used jointly with CC2, CC3, for determining adequate cover, concealment and observation (see subroutine CCO).

Q1  
Q2  
Q3

Coefficients, non-negative and summing to 1, used to determine the merit value of a point in the movement area (See subroutine CCO).

FIRING OPTIONS (See FIREOP)

FOTB(I,J,K)

Firing options for the base of fire where I - the average suppression state of the base of fire, J - the average suppression state of the unit they are supporting, and K - 1 for attackers, K - 2 for defenders.

FOTM(J,K)

Firing options for the unit being supported by the base of fire where J is the average suppression state of the unit and K - 1 for attackers, K - 2 for defenders

SUPPRESSION

DSUST (J,K)

Defines suppression state J as a function of  $P_{HIT}$  per minute; K - 1 defender, K - 2 attacker (See SUPN)

SUFAC(I,J)

Contains degradation factors J each suppression state (I); J - 1 firing rate; J - 2 aiming accuracy; J = 3 moving; J = 4 hand grenades

WITHDRAWAL

NSECTR

Number of angular increments (through a half arc of  $60^\circ$ ) between middle trial point and extreme trial point (use to select a rally point). (See RPT)

Table 3-1, Itemlist Inputs (Sheet 21)

|   |  |
|---|--|
| Withdrawal (Cont'd)                             |  |
| DWDR  | Radius of circular array of trial points for withdrawing to rally point  |
| CARFR   | Maximum allowable value of the ratio:<br><br>$\frac{\text{number of casualties carried}}{\text{number of members carrying}}$   |
| C1  | Maximum admissible ratio of current food per man to initial food for extraction  |
| C2  | Maximum admissible ratio of current water per man to initial water per man for extraction  |
| LDAYS   | Minimum admissible number of days elapsed for extraction   |
| <u>DEFENDER REACTION (See Subroutine REACT)</u> |  |
| KDEFOP  | Defender option index (after detecting attacker)<br>1 Withdraw at top speed<br>2 Deploy in place<br>3 Start firing in place<br>4 Ignore detection<br>5 Rotate formation and stop<br>6 Deploy with stealth to new point |

Table 3-1, Namelist Inputs (Sheet 22)

ATTRIBUTES

XATT(I,J,K)

Personnel attributes I for each man J, K = 1 for attackers  
K = IT + 1 for defenders, where IT is the target number 1-4

I: is the attribute of the Patrol Member

1 Team number  
2 Weapon number (See WTS in Weapon Supply DATA BASE)

3 Current ammunition supply (rounds)

4 Casualty status: 0 = not a casualty

1 = minor wound

2 = major wound

3 = dead

5 Firing status:

0 = not firing

1 = area fire

2 = point fire

6 Current suppression state

7 Current X coordinate (meters)

8 Current Y coordinate (meters)

9 Next X coordinate (meters)

10 Next Y coordinate (meters)

11 Height (meters)

12 Width (meters)

13 Current posture:

1 = standing

2 = crouching

3 = prone

14 Moving Status (0 = stopped, 1 = moving

normally, 2 = moving at top speed)

15 Maneuver unit to which the element belongs

16 Number of rounds remaining in magazine

17 Function in Patrol: 1 = Patrol Leader

2 = Asst. Patrol Leader

3 = Machine Gunner

4 = Grenade Launcher

5 = Rifleman

18 Movement rate of each individual

Table 3-1, NameList Inputs (Sheet 23)

## Attributes (Cont'd)

- 19 Individual's assignment: 1 = if in base of fire  
2 = if in maneuver unit
- 20 Initial ammunition supply
- 21 Weapon type: 1 = point fire  
2 = area fire
- 22 Position in fire team
- 23 Secondary Weapon Carried: 13 = Hand Grenade  
0 = None
- 24 Hand Grenade Supply
- 25 Smoke Grenade Supply

## YATT(I,J,K)

Maneuver unit attributes I for each maneuver unit J, K = 1 for attackers, K = IT + 1 for defenders, where IT is the target number 1-4

- I: 1 = Movement type, loads MOVTYPE  
2 = Number of fire teams in the maneuver unit  
3 = Index M used to specify which of the particular permutation used to assign fire teams to their positions within their maneuver unit  
4 = Number of patrol member acting as leader of the maneuver unit. Loads KPEN  
5 = Maneuver Unit assignment, Loads IBF  
1 = base of fire  
0 = moving

ATTRIBUTES (continued)

ZATT(1,K)

Attacker defender attribute I, K = 1 for SLAF, K = IT + 1 for target IT, where IT is the target number 1-4

- I: 1 = Number of maneuver units in the patrol  
 2 = Patrol mission. Loads MISS  
 3 = Availability of external fire support to patrol;  
     0 = not available  
     1 = available. Loads EFSA  
 4 = Patrol member number of patrol leader. Loads NPL  
 5 = Patrol member number of assistant patrol leader.  
     Loads NAPL  
 6 = Relative weight factor assigned to semi-automatic  
     weapons in defining firepower for the attacking  
     patrol. Loads SCEMI(1)  
 7 = Relative weight factor assigned to semi-automatic  
     weapons in defining firepower for the defending  
     patrol. Loads CSEMI(2)  
 8 = Relative weight factor assigned to automatic  
     weapons in defining firepower for the attacking  
     patrol. Loads CAUTO(1)  
 9 = Relative weight factor assigned to automatic  
     weapons in defining firepower for the defending  
     patrol. Loads CAUTO(2)  
 10 = Relative weight factor assigned to grenades in  
     defining firepower for the attacking patrol.  
     Loads CGREN(1)  
 11 = Relative weight factor assigned to grenades in  
     defining firepower for the defending patrol.  
     Loads CGREN(2)  
 12 = Firepower ratio which if exceeded will result in a  
     break contact decision for defenders. Loads FPMAX(1)  
 13 = Firepower ratio which if exceeded will result in a  
     break contact decision for attackers. Loads FPMAX(2)

Table 3-1, Hamelist Inputs (Sheet 25)

## ATTRIBUTES (CONTINUED)

- 14 = Maximum number of rounds per man which will result in a break contact decision for attacking patrol. Loads RLIM (1)
- 15 = Maximum number of rounds per man which will result in a break contact decision for defending patrol. Loads RLIM (2)
- 16 = Casualty fraction which it exceeded will result in a break contact decision for attacking patrol. Loads CFMAX(1).
- 17 = Casualty fraction which if exceeded will result in a break contact decision for defending patrol. Loads CFMAX(2).
- 18 = Value of the loss of key personnel (see definition of L(K) ) which will result in a break contact decision for attackers. Load LKP(1)
- 19 = Value of the loss of key personnel (see definition of L(K) ) which will result in a break contact decision for defenders. Load LKP(2)
- 20 = Elapsed engagement time which will result in a break contact decision for attacking patrol. Loads TLIN(1)
- 21 = Elapsed engagement time which will result in a break contact decision for defending patrol. Loads TLIN(2)
- 22 = Range between units which will result in a break by defending patrol. Loads DISTL
- 23 = Orientation angle of patrol configuration if stationary, as required by subroutine FORMST

Table 3-1, Namelist Inputs (Sheet 26)

| XLAAM(I,J) | WEAPON  |               |
|------------|---|---------------|
|            | Contains lethal areas for grenade Type J      |               |
| I = 1      | Lethal area for minor wound - target position | 1 = standing  |
| 2          | Lethal area for minor wound - target position | 2 = crouching |
| 3          | Lethal area for minor wound - target position | 3 = prone     |
| 4          | Lethal area for major wound - target position | 1 = standing  |
| 5          | Lethal area for major wound - target position | 2 = crouching |
| 6          | Lethal area for major wound - target position | 3 = prone     |
| 7          | Lethal area for death wound - target position | 1 = standing  |
| 8          | Lethal area for death wound - target position | 2 = crouching |
| 9          | Lethal area for death wound - target position | 3 = prone     |

Table 3-1, Namelist Inputs (Sheet 27)

## WEAPONS (Continued)

| WCHAR(I,J) | Weapon characteristics I for each weapon number J.          |
|------------|---|
| 1          | Maximum range (meters)                                      |
| 2          | Minimum range (meters)                                      |
| 3          | Rounds per trigger pull - point fire                        |
| 4          | Actual firing rate - point fire (trigger pulls/min)         |
| 5          | Rounds per trigger pull - area fire                         |
| 6          | Actual firing rate-area fire (trigger pulls/min)            |
| 7          | P given hit indicator (or value)                            |
| 8          | Air error indicator   |
| 9          | $\sigma X1$ (mils) used if aim error indicator              |
| 10         | $\sigma Y1$ (mils) is zero                                  |
| 11         | $\sigma X2$ (mils)  |
| 12         | $\sigma Y2$ (mils)  |
| 13         | $\mu X3$ (mils)   |
| 14         | $\mu Y3$ (mils)   |
| 15         | $\sigma X3$ (mils)  |
| 16         | $\sigma Y3$ (mils)  |
| 17         | Distance between aimpoints - area fire (meters)             |
| 18         | Maximum number of aimpoints in area of responsibility       |
| 19         | - area fire   |
| 20         | Minimum number of aimpoints in area of responsibility       |
| 21         | - area fire   |
| 22         | Vertical aimpoint above ground level for area fire (meters) |
| 23         | Lethal area indicator (= 0 except for grenades)             |
| 24         | Weapon type for area assignment                             |
| 25         | (1 = semi-automatic, 2 = automatic, 3 = grenades)           |
| 26         | Weapon type for firing allocating weight factors            |
| 27         | (1 = semi-automatic, 2 = automatic, 3 = grenades)           |
| 28         | Weapon magazine capacity (rounds)                           |
| 29         | Loading time (Seconds)                                      |

Table 3-1, Namelist Inputs (Sheet 28)

MINES

|                   |   |
|-------------------|---|
| NBR               | = Number of mines deployed by Subject Patrol  |
| LGTH              | = Length of mine field (meters)   |
| XCENT<br>YCENT    | = Coordinates of the centroid of the mine field deployment line segment. (line along which mines are deployed). (Map Coordinates) |
| TAK               | = Angle that the mine field deployment lines makes with the X-axis. Positive counterclockwise                                     |
| XLAAW<br>(I,LAIC) | = Lethal area for mines. See table XLAAW, Volume IV   |
| LAIC              | = Lethal area indication for mines. Points to appropriate lethal area column for mines in table XLAAW                             |
| XENGA<br>YENGA    | = Coordinates of engagement point (Map Coordinates)   |

EXTERNAL FIRE SUPPORT (For Combat Model)

|        |   |
|--------|---|
| T1     | = The time to make a request for EFS plus aiming calculation time, and time for flight of the shells                                |
| T2     | = The time to communicate open fire request plus the time of the flight of the shells given that attack has been previously planned |
| T3     | = The time delay between each volley of shells  |
| SAFDIS | = The safe-distance radius between the SIAF and target for an EFS attack  |

Table 3-1, Hamelist Inputs (Sheet 29)

## External Fire Support (Cont'd)

**NVOLLEY** = The total number of volleys in the EFS attack  
**SIGMDIS** = The error due to ballistic dispersion expressed as the standard deviation.  
**JARTL** = Variable whose value (1, 2, 3, 4, 5, 6) specifies which type of artillery or air support is used:  
           1 = 4.2 inch mortar  
           2 = 155 MM Howitzer  
           3 = 105 MM Howitzer  
           4 = 175 MM Gun  
           5 = 8 inch Howitzer  
           6 = Air support

**MAEE (Z,J)**

Lethal radius of selected ammo against Posture (Z) for kill level J  
 J=1 death, J=2 major wound, J=3 minor wound.

**NSUPP**

= Suppression state assigned to enemy patrol after completion of the first volley of EFS

DATA BASE  
SET UP

| <u>Symbol</u> | <u>Definition</u>  | <u>Units</u> | <u>Default Value</u> |
|---------------|--|--------------|----------------------|
| IPOS          | Total number of different personnel postures in set  |              |                      |
| SEGMIN        | Minimum segment length for which a segment is considered negligibly small  | meters       | 0.1                  |
| DSTEP         | The maximum step size to be used in a mini-segment. The highest velocity moving feasible target will define the time step size to use for detailed | meters       | 10.                  |

Table 3-1, Iamelist Inputs (Sheet 30)

| Data Base Set Up (Cont'd) |  |                       |
|---------------------------|--|-----------------------|
| <u>Symbol</u>             | <u>Definition</u>  | <u>Units</u>          |
|                           | detection to assure, at most, a step size of DSTEP for any target or for SIAF (the value must be > 0)  |                       |
| MAXDIS                    | Maximum distance patrol can move in any event time   | Meters                |
|                           | <u>FORMATION</u> (Reconnaissance Only)   |                       |
| FORMS(I,J,IFS)            | The location within a SIAF patrol for each of the elements J for each type of special formation IFS (used by Subroutine DETECT when man-to-man detection is desired) | meters                |
|                           | where: I = 1 is the X location of element J relative to the J = 1 element<br>I = 2 is the Y location of element J relative to the J = 1 element                      |                       |
|                           | <u>HUMAN MAINTENANCE</u>   |                       |
| BSAREA                    | Body surface area  | square ft             |
| CONCAP                    | Convective capacity content  | BTU/lb <sup>o</sup> F |
| CPRAT (L)                 | Energy expenditure rate for type L check point (rest, recon, sleep, etc. - subroutine HUMAN)   | meters                |
|                           |  | See Subroutine HUMAN  |

Table 3-1, Namelist Inputs (Sheet 31)

## Human Maintenance (Cont'd)

|        |  |  |                      |
|--------|--|--|----------------------|
| SIGFFR | Heat transfer constant: $\sigma * F_{ae} * f_r$<br>where | $\frac{\text{BTU}}{\text{ft}^2 \cdot \text{hr}} \left( \frac{^\circ\text{R}}{4} \right)^4$ | $0.1103 \times 10^8$ |
|        | $\sigma$ = Stephen-Boltzman constant                     |  |                      |
|        | $F_{ae}$ = Shape emissivity factor                       |  |                      |
|        | $f_r$ = Radiation area factor                            |  |                      |
| RHOH   | Air density  | lbs/cu ft  | 0.075                |
| P      | Barometric pressure                                      | mm Hg  | 760.                 |
| To     | Base film temperature, absolute                          | F  | 536.                 |
| Po     | Standard pressure  | mm Hg  | 760.                 |
| RPE    | Vapor resistance, air                                    | in. of air   | 0.24                 |
| RPG    | Vapor resistance, garments                               | in. of air   | 0.50                 |
| XMMAX  | Maximum SIAF personnel energy expenditure rate (BTU/hr)  |  |                      |

Table 3-1, Hamelist Inputs (Sheet 32)

## HUMAN MAINTENANCE (cont.)

| <u>Symbol</u>  | <u>Definition</u>   | <u>Units</u> | <u>Default Value</u>  |
|----------------|---|--------------|-----------------------|
| FURAT(L)       | Food consumption energy expenditure rate for type L checkpoint (rest, recon, sleep, etc. - see Subroutine HUMAN).                     | BTU/hr       | See Subroutine LOGIS  |
| LAMDAE         | Heat of vaporization  | BTU/lb       | 1080.                 |
| STS            | Skin temperature  | °F           | 95.                   |
| PS             | Vapor Pressure at skin  | in. Hg       | 42.                   |
| <u>TERRAIN</u> |   |              |                       |
| SL1            | Limiting value on terrain surface quadratic coefficient - a value close to zero indicates the terrain surface is approximately linear |              | $5 \times 10^4$       |
| SL2            | Limiting value of slope differences   |              | 0.05                  |
| DMT(I,K)       | Density of micro-relief feature of type K (positive undulations, negative undulations, boulders) in micro-relief class I (I=1,...,5). | number/acre  | See Subroutine MICROT |
| RHOI(II,U)     | Density of vegetation features type U (1=grass, 2=brush, 3=tree trunk, 4=tree crown) in vegetation class II.                          | number/acre  | See Subroutine VEGCON |
| RMAX(II,U)     | Range at which a target has unity probability of being completely concealed by vegetation features of type U in class II.             | meters       | See NAMELIST          |

Table 3-1, Namelist Inputs (Sheet 33)

# TERRAIN (Cont.)

| <u>Symbol</u> | <u>Definition</u>  | <u>Units</u> | <u>Default Value</u>  |
|---------------|--|--------------|-----------------------|
| PMTMAX(I,L)   | Range at which a target has unity probability of being completely concealed by micro-relief features of type L (1=positive undulations, 2=negative undulations, 3=boulders) in micro-relief class I (see Subroutine MICROT). | meters       | See Subroutine MICROT |
| W(I,U)        | Width of vegetation features of type U (1=grass, 2=brush, 3=tree trunks, 4=tree crowns) in vegetation class I (see Subroutine VEGCON).   | meters       | See Subroutine VEGCON |
| WMT(L,K)      | Width of micro-relief feature of type K (1=positive undulations, 2=negative undulations, 3=boulders) in micro-relief class L (see Subroutine MICROT)   | meters       | See Subroutine MITFEA |
| DSW11         | Water depth in vegetation class 13 - sparse swamp.   | meters       | 1.0                   |
| DSW12         | Water depth in vegetation class 14 - dense swamp.  | meters       | 1.0                   |
| DRICE         | Water depth in vegetation class 16 - rice field  | meters       | 0.3                   |
| H(I,U)        | Height above surface of vegetation features (1=grass, 2=brush, 3=tree trunks, 4=crowns of trees) for vegetation class I (I=1,...,16).  | meters       | See Subroutine VEGCON |

|-------------------|---|----------------------|----------------------|
| <u>Symbol</u>     | <u>Definition</u>   | <u>Units</u>         | <u>Default Value</u> |
| SGMTAB            | Sigma, Map Terrain Association, Best. For the area of SIAF operation this value represents the standard deviation of the best (minimum) distances within which SIAF can determine its location at any point on its route (except a check-point) by Map Terrain Association, provided that visibility and light level are adequate (i.e., ALL = ALLB, VISM = VISMB). | meters               | 50.                  |
| SGMTAW            | Sigma, Map Terrain Association, Worst. Analogous to SGMTAB, but for poor visibility (VISM = VISMW, ALL = ALLW). This term represents the limit on position location by map terrain association.   | meters               | 200.                 |
| VISMB             | Meteorological Visibility, Best. Visibility (VISM) at which the surrounding terrain features can be seen and identified in sufficient detail to allow the SIAF location to be determined (by Map Terrain Association) to approximately the distance given by the one sigma value of SGMTAB.   | meters               | 13.                  |
| VISMW             | Meteorological Visibility, Worst. Similar to VISMB described above, but for the "worst" visibility. If VISM = VISMW then SGMTA = SGMTAW. If VISM < VISMW then SIAF location cannot be determined by Map Terrain Association.  | meters               | 300.                 |

Table 3-1, Namelist Inputs (Sheet 36)

NAVIGATION (cont.)

| <u>Symbol</u> | <u>Definition</u>   | <u>Units</u> | <u>Default Value</u> |
|---------------|---|--------------|----------------------|
| ALLW          | The "worst" value of Ambient Light Level (ALL) for Map Terrain Association. If ALL > ALLW then SIAF location cannot be determined by Map Terrain Association.   | ft lamberts  | $4 \times 10^3$      |
| ITACOS        | Average time necessary to get an air craft on-site if PPLS is to be used  | seconds      | 900.                 |
| ALLB          | The "best" value of Ambient Light Level (ALL) for map-terrain-association (i.e., that value of ALL at which SIAF location can be determined to approximately SGM TAB provided that visibility is good). If ALL > ALLB then it is assumed that ALL > ALLB. | ft lamberts  | $5 \times 10^3$      |
| PMC           | Point-on-map Error (Constant Component). Error associated with putting the believed SIAF location on the map as a point (25 meters suggested for 1:50,000 map; other map scales are automatically converted internally).                                  | meters       | 25.                  |
| PMR           | Point-on-map Error (component that increases with range traveled). (25 meters for 1:50,000 map; other values converted internally).   | meters       | 25.                  |
| RC            | Range Error Constant. Average error associated with estimating range traveled (by pace count), expressed as % of distance traveled since last check-point.  |              | 4.                   |

Table 3-1, Namelist Inputs (Sheet 37)

| <u>NAVIGATION (cont.)</u> |  |              |                      |
|---------------------------|--|--------------|----------------------|
| <u>Symbol</u>             | <u>Definition</u>  | <u>Units</u> | <u>Default Value</u> |
| RCTAR                     | Range Error Constant Target Estimate.<br>Average error ( $\sigma$ ) associated with visual estimation of the range to a sighted target, expressed as % of estimated range. |              | 10.                  |
| bE                        | Base Error. ( $\sigma_{bE}$ ). Average distance between SIAF location and exact center of checkpoint location when SIAF believes it is at checkpoint.                      | meters       | 25.                  |
| AA                        | Average Compass reading error (assume more than one compass reading is taken for mission leg).   | degrees      | 1.85                 |
| AEQ                       | Effect of special equipment on estimating average compass reading error.   | degrees      | 0.                   |
| ATTAR                     | Angle error, target estimate. Average compass reading error of bearing to target.  | degrees      | 4.                   |
| GR                        | Grid Reading Error. Introduced by translating the point on the map into eight-digit grid readings (25 meters for 1:50,000 map; other values converted).                    | meters       | 25.                  |
| ATER                      | Effect of terrain on estimating average compass reading error.   | degrees      | 0.                   |

NAVIGATION (cont).

| <u>Symbol</u>        | <u>Definition</u>  | <u>Units</u> | <u>Default Value</u>  |
|----------------------|--|--------------|-----------------------|
| RTER                 | Effect of terrain on estimating range traveled.  |              | 0.                    |
| REQ                  | Effect of special equipment on estimating range traveled.  |              | 0.                    |
| ITDRPM               | Average time for SIAF to determine its position by dead reckoning, put point on map, and read eight digit grid coordinates.                          | seconds      | 60.                   |
| ITHMTA               | Average time necessary to attempt position location by map-terrain association with good light and visibility, given general area by dead reckoning. | seconds      | 120.                  |
| ITINTAR              | Average time necessary to estimate range and bearing of target visually detected.  | seconds      | 30.                   |
| ITPLSA               | Average time for an accurate (CEP = 50 meters) navigational fix by PPLS once A/C is on site.   | seconds      | 120.                  |
| ITPLSQ               | Average time for a "quick" navigational fix (CEP = 150 meters) by PPLS once A/C is on site.  | seconds      | 900.                  |
| <u>MOVEMENT RATE</u> |  |              |                       |
| VTYP                 | Typical SIAF movement rate. (See Subroutine MVRATE)  |              | .3 meters per second  |
| TMR(I,J)             | Movement rates for night (J=1) and day (J=2) over terrain slopes satisfying for various slope values I   | km/hr        | See Subroutine MVRATE |

Table 3-1, Hamelist Inputs (Sheet 39)

# MOVEMENT RATE (Cont'd)

| <u>Symbol</u> | <u>Definition</u>  | <u>Units</u> | <u>Default Value</u>  |
|---------------|--|--------------|-----------------------|
| TMR(I,3)      | Slope limits defining movement rate as a step function   |              | See Subroutine MVRATE |
| VEGF(I)       | Movement rate degradation factor for vegetation class I (I = 1,...,16).  |              | See Subroutine MVRATE |
| SOILF(I,J)    | Movement rate degradation factor for soil type J (see Subroutine SOIL), for wet conditions (I=1) and dry conditions (I=2).                 |              | See Subroutine MVRATE |
| ALIM(I,J)     | Night and day limits of ambient light level for a movement rate degradation (lower limit I=1, upper limit I=2, night J=1, day J=2).        | ft lamberts  | See Subroutine MVRATE |
| ALLF(I,J)     | Movement rate degradation factor for night (J=1) and day (J=2) for various values (I=1,2,3; see Subroutine MVRATE) of ambient light level. |              | See Subroutine MVRATE |
| VEGC(2,I)     | The speed adjustment factor for the vegetation class II (integer). (Used by target Only)   |              | See MOVET             |

20660-6002-R0-00  
Page 3-41  
Revised December 1973

## Movement Rate (Cont'd)

|     |  |
|-----|--|
| WDC | Weighting factor associated with detection for critical movement problem |
| WDM | Weighting factor associated with detection for marginal movement problem |
| WTC | Weighting factor associated with time for critical movement problem      |
| WTM | Weighting factor associated with time for marginal movement problem      |

AURAL DETECTION

| <u>Symbol</u> | <u>Definition</u>   | <u>Units</u> | <u>Default Value</u> |
|---------------|---|--------------|----------------------|
| ATTEN(J)      | The attenuation coefficient for sound passing through solid growth of feature type J. This will be modified by growth density in the subroutine (1=grass, 2=brush, 3=tree trunk, 4=tree crown). | dB/meter     | See Subroutine AURAL |
| VEGC(4,II)    | The background noise level for vegetation class II in the daytime.  | dB           | See Subroutine AURAL |
| VEGC(5,II)    | The background noise for vegetation class II in the nighttime.  | dB           | See Subroutine AURAL |
| VEGC(6,II)    | The noise generated by one man moving in vegetation class II.   | dB           | See Subroutine AURAL |
| VEGC(7,II)    | The noise generated by one man not MOVING IN VEGETATION class II.   | dB           | See Subroutine AURAL |
| VEGC(8,II)    | The incremental wind background noise for vegetation class II.  | dB/knot      | See Subroutine AURAL |

Table 3-1, Hamelist Inputs (Sheet 41)

| <u>DETECTION</u> (See Subroutine DETECT) |  |                |                      |
|--|--|----------------|----------------------|
| <u>Symbol</u>                            | <u>Definition</u>  | <u>Units</u>   | <u>Default Value</u> |
| ANGID                                    | Angular subtense required for identification of a target   | minutes of arc | 12.                  |
| CRECOG                                   | Contrast ratio required for recognition of a target.   |                | 1.                   |
| DBACK                                    | Distance behind target considered for background calculations.   | meters         | 50.                  |
| TDMIN                                    | Time interval in which detections can be considered simultaneous.  | seconds        |                      |
| WR                                       | Fractional target width required to be visible for target recognition.   |                | 0.5                  |
| SECT<br>(I,IND,1)                        | Sector of scan for the case of both patrols moving or both patrols stopped, where I=1 for the angular left bound for the sector of responsibility for the current sector index IND (IND=1,2,3,4), and I=2 is the angular right bound.  |                | See DETECT           |
| SECT<br>(I,IND,2)                        | Sector of scan for the case of stationary observer and moving target where I and IND are as above. This variable is an adjustment to the scan sector due to peripheral vision being able to pick up targets at a much wider angle from forward than is nominal for a fixed target (see Subroutine DETECT). |                | See DETECT           |

Table 3-1, Namelist Inputs (Sheet 42)

| <u>Symbol</u>     | <u>DEFLECTION</u><br>(See Subroutine DETECT)   | <u>Units</u>   | <u>Default Value</u> |
|-------------------|--|----------------|----------------------|
| ANGID             | Angular subtense required for identification of a target   | minutes of arc | 12.                  |
| CRECOG            | Contrast ratio required for recognition of a target.   |                | 1.                   |
| DBACK             | Distance behind target considered for background calculations.   | meters         | 50.                  |
| TDMIN             | Time interval in which detections can be considered simultaneous.  | seconds        |                      |
| WR                | Fractional target width required to be visible for target recognition.   |                | 0.5                  |
| SECT<br>(I,IND,1) | Sector of scan for the case of both patrols moving or both patrols stopped, where I=1 for the angular left bound for the sector of responsibility for the current sector index IND (IND=1,2,3,4), and I=2 is the angular right bound.  |                | See DETECT           |
| SECT<br>(I,IND,2) | Sector of scan for the case of stationary observer and moving target where I and IND are as above. This variable is an adjustment to the scan sector due to peripheral vision being able to pick up targets at a much wider angle from forward than is nominal for a fixed target (see Subroutine DETECT). |                | See DETECT           |

| <u>COMMUNICATION</u> |   |            |
|----------------------|---|------------|
| TUSE                 | Average external communication message duration   | minutes    |
| XDBINS               | Sound level increase during attempt of external communication                               | dB         |
| ICPER                | Length of communications period   | hours      |
| FREQ                 | Transmitter frequency of the patrol radio   | -          |
| PT                   | Transmitter output power  | mw         |
| TPOWR                | Transmission power requirements   | amps       |
| RPOWR                | Reception power requirements  | amps       |
| RNF                  | Receiver noise figure   | dB         |
| BETA                 | Receiver bandwidth  | Kilocycles |
| BLIFE                | Battery life for single radio (assuming a 9:1 ratio of receiving time to transmitting time) | Hours      |
| NBAT                 | Number of batteries carried per radio.  |            |
| NRAD                 | Total number of radios carried by SIAF  |            |

Table 3-1, Namelist Inputs (Sheet 47)

DYNAMIC ROUTE (See Subroutine DROUTE)

|        |   |        |
|--------|---|--------|
| IDELA  | 0 if point A, B, C, D, or E is to be deleted  |        |
| IDELB  | 1 if point A, B, C, D, or E is not deleted  |        |
| IDELC  |   |        |
| IDELD  |   |        |
| IDELE  |   |        |
| RAVOID | Radial distance from XAVOID, YAVOID with which all grid points are to be deleted (enter 0 if no such position).                     | meters |
| XAVOID | X coordinate of position for deletion of grid points  |        |
| YAVOID | Y coordinate of position for deletion of grid points  |        |
| RAVODD | Radial distance from XAVODD, YAVODD within which all grid points are to be deleted (enter 0 if no such position - second position). | meters |
| XAVODD | X coordinate of second position for deletion of grid points   |        |
| YAVODD | Y coordinate of second position for deletion of grid points   |        |
| GSAPRX | Approximate desired grid points spacing   | meters |
| GSAPXX | Approximate desired spacing for second stage grid (LFLOBJ = 1, I. GRID = 1)   | meters |

Table 3-1, Namelist Inputs (Sheet 48)

|                        |   |
|------------------------|---|
| Dynamic Route (Cont'd) |   |
| DSA                    | First significant range from enemy position XPPT, YPPT; enter only if DYWT (9,MI) $\neq$ 0  |
| DSAA                   | First significant range from position XPPTT, YPPTT; enter only if DYWT (8,MI) $\neq$ 0      |
| DMOR                   | Second significant range from enemy position XPPT, YPPT, enter only if DYWT (9,MI) $\neq$ 0 |
| DMORR                  | Second significant range from position XPPTT, YPPTT; enter only if DYWT (8,MI) $\neq$ 0     |
| RFSAA                  | Risk factor associated with DSAA.   |
| RFMOR                  | Risk factor associated with DMOR  |
| RFMORR                 | Risk or benefit factor associated with DMORR  |
| RFSAA                  | Risk factor associated with DSA   |
| NPAR                   | Number of parameters considered in the determination of path utility                        |

DYWT(IPAR,MI) Weight Factors for Assumed Missions; relative importance of parameter IPAR

MI: Mission Situation

- 1 = Reconnaissance - detect and identify suspected enemy but avoid encounter
- 2 = Reconnaissance - avoid enemy and proceed as fast as possible
- 3 = Combat - avoid detection and identification by the enemy

Table 3-1, Namelist Inputs (Sheet 49)

## Dynamic Route (Cont'd)

## IPAR:

- 1 = Movement Time
- 2 = SIAF Detects Enemy
- 3 = SIAF Identifies enemy
- 4 = Enemy detects SIAF
- 5 = Enemy identifies SIAF
- 6 = SIAF cover
- 7 = SIAF Concealment
- 8 = Distance from Enemy (2)\*\*
- 9 = Distance from Enemy (1)\*\*

\*\* The enemy locations can be used; however, the ninth parameter calculation refers to the same enemy position as the calculation of detection, identification, cover, and concealment.

CBDYWT (IPAR, ICB) The weight associated with parameter IPAR while movement type ICB is in progress (Same definition as DYWT above; used for combat)

Table 3-1. Namelist Inputs (Sheet 50)

EXTERNAL FIRE SUPPORT (for EFS Only Mission)

|        |   |               |
|--------|---|---------------|
| JNF    | Total number of firings   |               |
| AIRC   | 1 - If FFAR's are helicopter launched<br>0 - If FFAR's are fixed wing aircraft launched |               |
| IPREP  | 0 Don't use prep fire<br>1 Use LZ prep fire (prep fire assumed only on the primary LZ)  |               |
| PL     | CBU bomblet pattern length  | meters        |
| PW     | CBU bomblet pattern width   | meters        |
| MLANGL | Mean launch angle of MG firing  | degrees       |
| MLRANG | Mean launch range of MG firing  | meters        |
| LANGLE | Launch angle of FFAR salvo  | degrees       |
| LRANGE | Launch range of FFAR salvo  | meters        |
| MAE(i) | Lethal area of selected ammo versus personnel in posture (i)                            | square meters |
| F(i,j) | Fraction of personnel in posture (i) for each firing                                    |               |
| TB1STR | System delay time before first round or volley is delivered after fire request          | sec           |
| TBRNDS | System delay time between subsequent rounds/volleys                                     | sec           |

Table 3-1. Namelist Inputs (Sheet 51)

EXTERNAL FIRE SUPPORT (cont.)

|        |  |        |
|--------|--|--------|
| NN(J)  | Number of rounds in each firing                                    |        |
| NROP   | Number of ordnance delivery passes, GP                             |        |
| NRS1P  | Number of rockets launched - first pass                            |        |
| NRS2P  | Number of rockets launched - second and subsequent passes          |        |
| NCB1P  | Number of CBU bomblets delivered, first pass                       |        |
| NCB2P  | Number of CBU bomblets delivered, second and all subsequent passes |        |
| NGPB   | Number of GP bombs delivered                                       |        |
| RPA    | Artillery range probable error (also used for combat)              | meters |
| RPECBU | CBU delivery error - range   | meters |
| RPEGPB | GP delivery error - range  | meters |
| DPE    | Artillery deflection probable error (also used for combat)         | meters |
| DPECBU | CBU delivery error - deflection                                    | meters |
| DPEGPB | GP delivery error - deflection                                     | meters |

#### 4.0 MODEL OUTPUTS

##### 4.1 RECONNAISSANCE MODEL OUTPUTS

The reconnaissance model output variables are defined in Table 4-1, and are listed according to the order in which they appear in the model output format. The method used to calculate these variables is described in subroutines SISTAT and SIWRT of Volume IV.

##### 4.2 COMBAT MODEL OUTPUTS

The combat model output variables are defined in Table 4-2. In the model, these variables are printed out during each even time thus giving the user a time history of the events which took place during the combat operation.

Table 4-1, Model Output Variables (Sheet 1)

| <u>Symbol</u> | <u>Definition</u>   | <u>Units</u> |
|---------------|---|--------------|
| IVOR(IT,1)    | The number of visual detections of target IT by SIAF.                             |              |
| SDEISR(IT,1)  | The visual detection success ratio of target IT by SIAF.                          |              |
| SSTVDR(IT,1)  | The mean visual detection range of target IT by SIAF.                             | meters       |
| SSSTVD(IT,1)  | The standard deviation of the visual detection range of target IT by SIAF.        | meters       |
| SISTVD(IT,1)  | Mean time of detection of target IT by SIAF.                                      | days,hrs,min |
| SSISTV(IT,1)  | Standard deviation of the time of detection of target IT by SIAF.                 | days,hrs,min |
| IAOR(IT)      | Number of aural detection cues associated with the visual detection of target IT. |              |
| IIVOR(IT,1)   | Number of identifications of target IT by SIAF.                                   |              |
| SIDSR(IT,1)   | Identification success ratio of target IT by SIAF.                                |              |
| SSTRR(IT,1)   | Mean identification range of target IT by SIAF.                                   | meters       |
| SSSTRR(IT,1)  | Standard deviation of the identification range of target IT by SIAF.              | meters       |
| SISTRT(IT,1)  | Mean time of identification of target IT by SIAF                                  | days,hrs,min |
| SSISTR(IT,1)  | Standard deviation of the time of identification of target IT by SIAF.            | days,hrs,min |
| IIAOR(IT,1)   | Number of aural detections of target IT by SIAF.                                  |              |

Table 4-1, Model Output Variables (Sheet 2)

| <u>Symbol</u> | <u>Definition</u>  | <u>Units</u> |
|---------------|--|--------------|
| SAURSR(IT,1)  | Aural detection success ratio of target IT by SIAF.                        |              |
| SSTADR(IT,1)  | Mean aural detection range of target IT by SIAF.                           | meters       |
| SSSTAD(IT,1)  | Standard deviation of the aural detection range of target IT by SIAF.      | meters       |
| SISTAD(IT,1)  | Mean time of an aural detection of target IT by SIAF.                      | days,hrs,min |
| SSISTA(IT,1)  | Standard deviation of the time of an aural detection of target IT by SIAF. | days,hrs,min |
| SCEPTA(IT)    | The mean target location CEP of target IT.                                 | meters       |
| SSCEPT(IT)    | Standard deviation of the target location CEP of target IT.                | meters       |
| IVOR(IT,2)    | The number of visual detections of SIAF by target IT.                      |              |
| SDETSR(IT,2)  | Visual detection success ratio of SIAF by target IT.                       |              |
| SSTVDR(IT,2)  | Mean visual detection range of SIAF by target IT.                          | meters       |
| SSSTVD(IT,2)  | Standard deviation of the visual detection range of SIAF by target IT.     | meters       |
| SISTVD(IT,2)  | Mean time of detection of SIAF by target IT.                               | days,hrs,min |
| SSISTV(IT,2)  | Standard deviation of the time of detection of SIAF by target IT.          |              |
| IIVOR(IT,2)   | Number of identifications of SIAF by target IT.                            |              |

Table 4-1, Model Output Variables (Sheet 3)

| <u>Symbol</u> | <u>Definition</u>  | <u>Units</u> |
|---------------|--|--------------|
| SIDSR(IT,2)   | Identification success ratio of SIAF by target IT.                                   |              |
| SSTRR(IT,2)   | Mean identification range of SIAF by target IT.                                      | meters       |
| SSSTRR(IT,2)  | Standard deviation of the identification range of SIAF by target IT.                 | meters       |
| SISTRI(IT,2)  | Mean time of identification of SIAF by target IT.                                    | days,hrs,min |
| SSISTR(IT,2)  | Standard deviation of the time of identification of SIAF by target IT.               | days,hrs,min |
| IIAOR(IT,2)   | Number of aural detections of SIAF by target IT.                                     |              |
| SAURSR(IT,2)  | Aural detection success ratio of SIAF by target IT.                                  |              |
| SSTADR(IT,2)  | Mean aural detection range of SIAF by target IT.                                     | meters       |
| SSSTAD(IT,2)  | Standard deviation of the aural detection range of SIAF by target IT.                | meters       |
| SISTAD(IT,2)  | Mean time of an aural detection of SIAF by target IT.                                | days,hrs,min |
| SSISTA(IT,2)  | Standard deviation of the time of an aural detection of SIAF by target IT.           | days,hrs,min |
| SLOSRI(IT,1)  | Percent of the time target IT is not detected by SIAF due to a relief intercept.     |              |
| SLOSV(IT,1)   | Percent of the time target IT is not detected by SIAF due to a vegetation intercept. |              |

Table 4-1. Model Output Variables (Sheet 4)

| <u>Symbol</u> | <u>Definition</u>   | <u>Units</u> |
|---------------|---|--------------|
| SLOSD(IT,1)   | Percent of the time target IT is not detected by SIAF due to insufficient range or light.   |              |
| SLOST(IT,1)   | Percent of the time target IT is not detected by SIAF due to insufficient time.   |              |
| SLOSRI(IT,2)  | Percent of the time SIAF is not detected by target IT due to a relief intercept.  |              |
| SLOSV(IT,2)   | Percent of the time SIAF is not detected by target IT due to a vegetation intercept.  |              |
| SLOSD(IT,2)   | Percent of the time SIAF is not detected by target IT due to insufficient range or light.   |              |
| SLOST(IT,2)   | Percent of the time SIAF is not detected by target IT due to insufficient time.   |              |
| SMVEL         | Mean movement rate of the SIAF patrol.  | km/hr        |
| SSVEL         | Standard deviation of the movement rate of the SIAF patrol.   | km/hr        |
| STIME         | Mean patrol duration.   | days,hrs,min |
| SSIYIM        | Standard deviation of the patrol duration.  | days,hrs,min |
| SPATDI        | Mean distance traveled by the SIAF patrol.  | km           |
| SSPATD        | Standard deviation of the distance traveled by the SIAF patrol.   | km           |
| SVEL(I)       | Patrol velocity histogram. This vector consists of 12 elements. In each element, the percent of time the patrol is moving is stored in increments of 0.2 of a kilometer per hour. |              |

Table 4-1, Model Output Variables (Sheet 5)

| <u>Symbol</u> | <u>Definition</u>   | <u>Units</u> |
|---------------|---|--------------|
| SCEPPM        | The mean patrol location CEP at checkpoints.  | meters       |
| SSDCEP        | Standard deviation of the patrol location CEP at checkpoints.                             | meters       |
| SITNAV        | Mean time for the patrol to determine its location.                                       | minutes      |
| SSDIT         | Standard deviation of the time for the patrol to determine its location.                  | minutes      |
| SATTEM        | Mean number of communication attempts.  |              |
| SSATTE        | Standard deviation of the number of communication attempts.                               |              |
| SSUCRA        | Mean communication success ratio of the patrol.   |              |
| SSSUCR        | Standard deviation of the communication success ratio of the patrol.                      |              |
| SAPCAD        | The percent of the communication power loss due to relief for communication failures.     |              |
| SAPCAF        | The percent of the communication power loss due to vegetation for communication failures. |              |
| SAPCAS        | The percent of the communication power loss due to range for communication failures.      |              |
| STTIE         | The mean time the communication receiver of the patrol is on.                             | days,hrs,min |
| SSTIM         | Standard deviation of the time the communication receiver of the patrol is on.            | days,hrs,min |
| STTUSE        | The mean time the transmitter of the patrol communication equipment was on.               | days,hrs,min |

Table 4-1, Model Output Variables (Sheet 6)

| <u>Symbol</u> | <u>Definition</u>   | <u>Units</u>   |
|---------------|---|----------------|
| SSTUS         | Standard deviation of the time the transmitter of the patrol communication equipment was on.        | days, hrs, min |
| AWPHR         | Ampere hours available at the beginning of the patrol.  | amp hrs        |
| SAMPHR        | Mean ampere hours used by the communication equipment during the patrol.                            | amp hrs        |
| SSAMPH        | Standard deviation of the ampere hours used by the communication equipment during the patrol.       | amp hrs        |
| FOOD          | Amount of food carried per patrol member at the beginning of the mission.                           | lbs/man        |
| H2O           | Amount of water carried per patrol member at the beginning of the mission.                          | lbs/man        |
| XP2           | Amount of ammunition carried per patrol member at the beginning of the mission.                     | lbs/man        |
| XP3           | Amount of ordnance other than ammunition carried per patrol member at the beginning of the mission. | lbs/man        |
| SFOODA        | Mean amount of food carried by each patrol member at the end of the patrol.                         | lbs/man        |
| SSF00D        | Standard deviation of the amount of food carried by each patrol member at the end of the patrol.    | lbs/man        |
| SH20A         | Mean amount of water carried by each patrol member at the end of the patrol.                        | lbs/man        |
| SSH20A        | Standard deviation of the amount of water carried by each patrol member at the end of the patrol.   | lbs/man        |

Table 4-1, Model Output Variables (Sheet 7)

| <u>Symbol</u> | <u>Definition</u>  | <u>Units</u> |
|---------------|--|--------------|
| SPAK2         | Mean amount of ammunition carried by each patrol member at the end of the patrol.                                      | lbs/man      |
| SSPAK2        | Standard deviation of the amount of ammunition carried by each patrol member at the end of the patrol.                 | lbs/man      |
| SPAK3         | Mean amount of ordnance other than ammunition carried by each patrol member at the end of the patrol.                  | lbs/man      |
| SSPAK3        | Standard deviation of amount of ordnance other than ammunition carried by each patrol member at the end of the patrol. | lbs/man      |
| SPDEGL        | The mean human performance degradation at the end of the patrol.   |              |
| SSPDEG        | Standard deviation of human performance degradation at the end of the patrol.  |              |
| SPDMAX        | The mean of the maximum human performance degradation experienced by the patrol during the mission.                    |              |
| SSPDMA        | The standard deviation of the maximum human performance degradation experienced by the patrol during the mission.      |              |
| SPDMIN        | The mean of the minimum human performance degradation experienced by the patrol during the mission.                    |              |
| SSPDMI        | The standard deviation of the minimum human performance degradation experienced by the patrol during the mission.      |              |
| SPDAVG        | The mean of the average human performance degradation experienced by the patrol during the mission.                    |              |

Table 4-1, Model Output Variables (Sheet 8)

| <u>Symbol</u> | <u>Definition</u>   | <u>Units</u> |
|---------------|---|--------------|
| SSPDAV        | The standard deviation of the average human performance degradation experienced by the patrol during the mission. |              |
| SSIGEN        | The mean of the energy expended per patrol member at the end of the patrol.                                       | BTU          |
| SSIGE         | The standard deviation of energy expended per patrol member at the end of the patrol.                             | BTU          |
| SSGMAX        | The mean of the maximum energy expended per patrol member during the mission.                                     | BTU          |
| SSSGMA        | The standard deviation of the maximum energy expended per patrol member during the mission.                       | BTU          |
| SSGMIN        | The mean of the minimum energy expended per patrol member during the mission.                                     | BTU          |
| SSGMI         | The standard deviation of the minimum energy expended per patrol member during the mission.                       | BTU          |
| SSGAVG        | The mean of the average energy expended per patrol member during the mission.                                     | BTU          |
| SSSGAV        | The standard deviation of the average energy expended per patrol member during the mission.                       | BTU          |
| PDPL0T(1)     | A vector in which is stored a time history of human performance degradation for the mission.                      |              |

Table 4-1, Model Output Variables (Sheet 9)

| <u>Symbol</u> | <u>Definition</u>   | <u>Units</u> |
|---------------|---|--------------|
| HTPLOT(I)     | A vector of times associated with the human performance values in PDPLOT. |              |
| JJTIME(I)     | A vector in which is stored the arrival time of SIAF at the checkpoints.  |              |
| AAALL(I)      | The vector in which is stored a time history of the light level.          |              |
| KKTIME(I)     | A vector of times associated with the light level data.                   |              |

Table 4-2, Combat Outputs (Sheet 1)

| <u>Symbol</u> | <u>Definition</u>   | <u>Units</u> |
|---------------|---|--------------|
| EFSTIME(L)    | Time vector containing times of scheduled arrivals of external fire support burst events.   | seconds      |
| AIMPTXY       | X-Y coordinates of external fire support bursts.  | meters       |
| XYMINES(M)    | X-Y coordinates of the deployment of the M <sup>th</sup> mine in a Claymore minefield.  | meters       |
| TMINES        | Time until target arrives in Claymore minefield.  | seconds      |
| TAKOP         | Target's direction of movement.   | radians      |
| ICOMFT        | 1 if firing is being conducted; 0 before and after firing   |              |
| MOVINF(IUN)   | Movement information flag maneuver unit IUN.<br>0 = if a new check point is needed.<br>1 = if the current check point is still in effect. |              |
| IGA(IUN)      | Current check point for maneuver unit IUN.  |              |
| NGA(IUN)      | Total check points for maneuver unit IUN until the next objective point.  |              |
| XYGA(I,IUN)   | X-Y coordinates of check point I for maneuver unit IUN  | meters       |
| INRPA(IUN)    |   |              |
| IMPA(IUN)     | Current objective point for maneuver unit IUN.  |              |

Table 4-2, Combat Outputs (Sheet 7)

| <u>Symbol</u> | <u>Definition</u>   | <u>Units</u> |
|---------------|---|--------------|
| NARP(IUN)     | Total number of objective points for maneuver unit IUN.                   |              |
| XYARP(N,IUN)  | X-Y coordinates of N <sup>th</sup> objective point for maneuver unit IUN. | meters       |
| KKK           | Maneuver unit that last arrived at a check point.                         |              |

## 5.0 SUBROUTINES

The SIAF model subroutines are presented in Table 5-1 and a brief summary of their function is presented in Table 5-2. The elevation data handling subroutines are presented in Table 5-3. This information is provided as an overview of the SIAF model subroutines. Details concerning the purpose, description, inputs, outputs, flow chart, and programming information are presented in Volumes II, III, V, and VI.

Table 5-1, SIAF Models and Associated Subroutines (Sheet 1)

|                       |                           |                               | EFSMIN                                    |

Table 5-2, SIAF Subroutines and Their Function (Sheet 1)

TERRAIN

- LOSVEG - Computes line-of-sight limit due to vegetation and relief
- VEGCON - Computes vegetation concealment
- MITFEA - Determines if a target is on a micro-relief feature
- MITLOS - Computes line-of-sight limit due to micro-relief
- MITCON - Computes micro-relief concealment
- ELEV - Calculates elevation of a particular terrain coordinate
- SLOPE - Calculates slope between two points in the AO
- LINOBS - Determines if there is an obstacle, or vegetation, micro-relief, or soil polygons between two points
- TERCON - Integrates terrain subroutines into one package
- MICSOL - Determines micro-relief, vegetation, and soil type about a particular terrain coordinate

WEATHER

- WETHR - Computes ambient light level, meteorological visibility, temperature, humidity, wind velocity, and rain/no rain verdict

TARGET

- TARMOV - Moves targets during the insertion operation
- TARGEN - Places targets on the map
- MOVET - Moves targets in accordance with the scenario during non-insertion operations

Table 5-2, SIAF Subroutines and Their Function (Sheet 2)

ANCILLARY AND DATA HANDLING

- MAIN - Provides logic to drive the SIAF model
- CASEIN - Converts military coordinates to computer coordinates and converts all times to seconds
- REPIN - Initializes subroutine variables to proper values at the start of a new replication
- RESTART - Provides for model execution to start and stop at preset points

MOVEMENT

- INSERT - Simulates an insertion operation
- SEGGEN - Generates SIAF movement segment
- TMDRVR - Computes time interval for driving the model if the segment length is zero
- MVRATE - Computes nominal patrol velocity and actual velocity based upon mission and time constraints
- DROUTE - Computes check points for dynamic movement

NAVIGATION

- NAV - Computes patrol location CEP and target location CEP if detection(s) have occurred

Table 5-2, SIAF Subroutines and Their Function (Sheet 3)

SURVEILLANCE/DETECTION

TARGET - Eliminates infeasible targets from detection calculations  
 AURAL - Determines aural detection verdict  
 STRACK - Simulates special sound effects such as truck tailgate noise  
 VISUAL - Determines visual detection verdict  
 DETECT - Integrates detection subroutines into one package

EXTERNAL FIRE SUPPORT (EFS)

EFS - Computes results of external fire support when EFS only mode is used  
 EFS1 - Simulates the effects of external fire support in combat mode  
 EFSTIM - Computes the event times for external fire support bursts  
 EFCAS - Determines which members sustained casualties from external fire support

SUPPLY MAINTENANCE

LOGIS - Updates available patrol food, water, and ammunition

HUMAN MAINTENANCE

HUMAN - Computes required food and water depending upon work performed and computes human performance degradation due to fatigue, body water loss, and body heat storage

Table 5-2, SIAF Subroutines and Their Function (Sheet 4)

OPTIMIZATION LOGIC

- OLOGIC - Provides an optimum array of objective points for attacking maneuver unit routes for ambush or attack
- OLOG4 - Assigns the nominal attack configuration based upon the tactical situation and patrol mission
- OLOG6 - Determines whether the observed patrol configuration is linear or perimeter and - in case of linear - the axes of maximum and minimum dispersion of position
- OLOG7 - Sets an array of trial points over which to search for an optimum deployment point for the case in which the defenders are moving to within engagement range
- OLOG8 - Sets an array of trial points over which to search for an optimum deployment point for the case in which the defenders are moving and the attackers must move to within engagement range of the line of movement of the defenders
- OLOG9 - Sets an array of trial points over which to search for an optimum deployment point for the case in which the defenders are stationary
- OLOG10 - Selects an optimum deployment point from an array of trial points set by OLOG7, 8, or 9

COMMUNICATIONS

- EXCOM - Calculates external communications statistics and updates battery supply
- IC - Integrates the fire IC subroutines and decides whether internal communications is available between maneuver units
- ICGRE - Checks and updates the maneuver leaders supply of signal grenades
- ICMSG - Selects a messenger

Table 5-2, SIAF Subroutines and Their Function (Sheet 5)

COMMUNICATIONS (cont.)

- ICLOS - Determines whether line-of-sight exists between two maneuver unit leaders
- ICRAD - Determines whether two maneuver units can communicate using radios
- ICAUR - Determines whether a receiver can detect an aural message

COMMAND AND CONTROL

- PDDS - Determines detection verdict(s) from the possible detection possibilities

Table 5-2, SIAF Subroutines and Their Function (Sheet 6)

| <u>TERRAIN (COMBAT)</u> |   |
|-------------------------|---|
| JETERR                  | - Determines whether the line of sight from the observer to the observed is obstructed by macro-relief, and if it is not, computes probabilities of cover and concealment (head to head, head to foot, foot to head, and foot to foot). |
| PCOVER                  | - Computes the probabilities of no cover and of complete cover for observer-target and target-observer.   |
| PCONCL                  | - Computes the probabilities of no concealment and of complete concealment for observer-target and target-observer.   |
| PEQTN                   | - Computes the probabilities of complete obstruction of observer and target and the probabilities of no obstruction of observer and target.   |
| <u>DECISION LOGIC</u>   |   |
| MISGEN                  | - Coordinates combat initialization and combat execution.   |
| CCO                     | - Evaluates cover, concealment, and observation of an observer's position with respect to the observed's position.  |
| DLOGIC                  | - Simulates engagement-avoid decision and defines General Combat.   |
| DLOG1                   | - Reads detection and identification statistics and specifies two patrols--one to be a potential attacker and the other a potential defender.   |
| DLOG2                   | - Determines whether a patrol is sufficiently remote from an enemy patrol to call for external fire support.  |
| DLOG3                   | - Determines whether the latest possible deployment time would occur before sunrise or the earliest after sunset.   |
| DLOG4                   | - Determines whether the relative movement of the two patrols would allow adequate time for the attacking patrol to move to deployment and then to deploy. Determines all reachable deployment points.                                  |
| DLOG5                   | - Searches for the nearest admissible deployment point for the case of a moving enemy patrol where the enemy patrol's line of movement is not within engagement range of the attacking patrol.  |

Table 5-2, SIAF Subroutines and Their Function (Sheet 7)

DECISION LOGIC (Cont'd)

- DLOG6 - Searches for the nearest admissible deployment point for the case of a moving enemy patrol where the enemy patrol's line of movement is within engagement range of the attacking patrol
- DLOG7 - Tests a trial deployment point for terrain admissibility
- DLOG8 - Tests a pre-deployment movement area for sufficient protectiveness
- DLOG9 - Evaluates protectiveness for movement at a trial point in an array over a pre-deployment movement area
- DLOG10 - Searches for the nearest admissible deployment point for the case of a stationary enemy patrol
- DLOG11 - Computes the SIAF velocity vector for SIAF on either a planned route or a dynamic route for the case in which SIAF is a potential defender

FIRE CONTROL/LETHALITY

- KILL - Controls the operation of the remaining fire control/lethality subroutines
- LETH - Allocates point fire weapons, assigns area fire as appropriate, assigns hand grenades as appropriate
- ARAS - Computes the area of responsibility for each firer and computes which targets are in each area of responsibility
- PKBRP - Computes a figure of merit for alternative firing strategies
- FALOC - Computes the optimum point fire allocations for all firers in the point fire mode
- NEXTC - Computes casualty data for the next attacker and defender casualty
- PTPTPK - Computes kill probability for each firer using a rifle or machine gun
- ARPTPK - Computes kill probability for each firer using a grenade launcher
- S1 - Computes the total single shot delivery error for each weapon type
- PKH - Computes the probability of kill given a hit
- SUPH - Computes individual suppression states

Table 5-2, SIAF Subroutines and Their Function (Sheet 8)

COMBAT FUNCTIONS AND C<sup>2</sup>

|         |  |
|---------|--|
| CHAIN   | - Provides logic to drive the combat model.  |
| MOVPLN  | - Generates dynamic route points between unit movement objective points.                           |
| MOVDRV  | - Computes movement rates and movement event times.  |
| FORMST  | - Computes coordinates of individuals for various formations.                                      |
| POSTURE | - Computes the posture of each individual.   |
| FIRATE  | - Computes firing rate of each individual based upon the ammunition remaining.                     |
| AMMOUP  | - Updates ammunition in the magazine and total ammunition remaining for each individual.           |
| FIREOP  | - Computes the firing option of each unit based upon the current suppression state of the unit.    |
| WSUBS   | - Provides logic for weapon substitution.  |
| BREAK   | - Provides logic for breaking contact.   |
| RPT     | - Computes withdrawal points for defending unit.   |
| WDR     | - Computes withdrawal points for attacking unit.   |
| CONMIS  | - Computes a continue the mission decision for SIAF after the combat operation has been completed. |
| REACT   | - Provides six defender reaction options after detection but before fire-fight                     |
| CREACT  | - Permits attacking unit to revise its plan before attack is initiated                             |
| MINES   | - Provides for a Claymore Mine ambush  |
| FIRIHT  | - Initiates fire-fight between an attacking and a defending unit                                   |
| EFSMIN  | - Updates the EFS event times  |

Table 5-3, SIAF Elevation Data Handling (Sheet 1)

ELEVATION DATA HANDLING

|         |   |
|---------|---|
| CONVERT | - Produces FORTRAN - compatible tapes from Defense Mapping Agency (TOPOCOM) Digital Topographic Tapes             |
| MAPGEN  | - Selects and/or thins terrain elevation data for the area of operation   |
| ROTATES | - Provides for rotation and change of interval distance between elevation points at a map area output from MAPGEN |
| CMREAD  | - Loads a selected section of the available map area into computer memory   |
| RERead  | - Condenses the input area elevations in computer memory  |

## 6.0 SAMPLE CASE

Sections 6.1 through 6.4 describe a test case which illustrates the use of the reconnaissance model while Sections 6.5 and 6.6 present a combat model test case.

As part of the SIAF program, a model verification plan was developed and a test using actual patrols was conducted. Concurrent with the test, the SIAF System Model was exercised for the purpose of simulating this test and providing data for comparison purposes. This section presents a sample case based upon the test scenario. Included is a qualitative description of the test, a description of the model input data consisting of terrain, weather, the SIAF operations plan, and the enemy situation, and a description of the outputs of the model.

### 6.1 QUALITATIVE DESCRIPTION OF THE TEST PROGRAM

The field test was conducted at the Hunter Liggett Military Reservation located near King City, California, a facility of the Combat Developments Command Experimentation Command headquartered at Fort Ord, California (Monterey). The test exercise was conducted in a relatively rugged and remote valley which is also a part of Los Padres National Forest. Figure 6.1 is a photograph of a map of the area of operations which represents a geographic area of approximately 17 square kilometers. The patrol mission-scenario (including an aggressor scenario) was developed by the test conductor employing inputs from the test team members. The mission was basically one of reconnaissance which consisted of surveillance of a road suspected of being an enemy supply route, by a SIAF patrol moving primarily at night along the high ground on one side of the valley. Combat was not entered or simulated and live ammunition was not carried.

As shown by Figure 6.1, the distance between the projected insertion and extraction points is approximately 6-1/4 kilometers; however, the route between checkpoints and projected patrol bases is not a straight line nor did the patrols follow a simple point-to-point route. The actual route traveled by each patrol was approximately 9 kilometers long.

Each patrol spent two days in an objective area near the center of the route. This area contained several OP's and bases among which the patrol moved. Aggressor activity existed in the area, some of which was along the roads. For experimental purposes, this area was instrumented to determine exact positions and ranges of detection between the SIAF patrols and the aggressor.

AREA OF OPERATIONS

1 KM 0.5 0

CONTOUR INTERVAL 20 FEET

● SIAF CHECKPOINTS AND BASES

Figure 6.1, SIAF Area of Operations  
Showing Patrol Checkpoints

The 5 1/2 day mission was performed by each of 20 patrol teams provided by the 3 participating services:

|                     |          |
|---------------------|----------|
| Army Special Forces | 10 teams |
| U. S. Marine Corps  | 5 teams  |
| U. S. Navy Seals    | 5 teams  |

Each six-man SIAF patrol team was given the same mission, checkpoints, and basing areas, and was exposed to the same aggressor scenario. Patrols moved primarily at night. During the day the patrols established bases from which they monitored the primary road or conducted related reconnaissance and surveillance activities. The sample case described herein (referenced as scenario 1) treats only the first of these patrol missions.

## 6.2 GENERATION OF BINARY TAPE 8

As described in Section 3.0, Binary Tape 8 is generated from card input. Because of the requirement to duplicate the test situation as closely as possible, detailed terrain and vegetation data were first gathered. This section describes that task.

As previously described in Section 2 4.1, the terrain resolution study for the Hunter Liggett area indicated a substantial increase in accuracy with 50-meter resolution as compared with that obtained for 100-meter resolution. Since the objective of the Hunter Liggett test was to validate the SIAF model, it was considered necessary to use 50-meter resolution. Since the only available digitized data were 100-meter resolution, a decision was made to input the elevation data for the area of operations shown in Figure 6.1 by hand. For this purpose, the map shown in Figure 6.1 was enlarged and a 50-meter grid was overlayed on the map. Then elevation data associated with each corner point of the grid were recorded on computer input sheets. The resulting 7,105 points took approximately two weeks to record. A namelist printout of these resulting data is shown in Figure 6.2. These data, which were used to generate Binary Tape 8, are in feet since the map used for this purpose (Reference 3) contained elevation information in these units. Data were subsequently converted to meters in the computer program.

It should be pointed out that Army digitized terrain tapes of various areas of the world exist. These tapes obviate the necessity of inputting

terrain data by hand as was done for this sample case, and normal use of the model for various SIAF studies would probably not require as extensive an effort as was undertaken for this project.

As with relief, considerably more effort than normally required was taken to input vegetation data since the objective of the simulation was to duplicate as best as possible the test situation. As described in Section 2.4.1, a vegetation survey of the Hunter Liggett area was conducted for the purpose of obtaining input data for this simulation. During this survey, aerial photographs of the area were obtained, a ground survey was conducted, and the vegetation in the area was categorized according to the classification scheme shown in Figure 2.7. From this information, the vegetation data for the 50-meter grid square resolution were recorded on computer input sheets. The last part of Figure 6.2 shows namelist printout of these data from which Tape 8 was generated. Because of the difficulties of correlating the aerial photograph with the map, this exercise took approximately three weeks; however, normal use of the model would require a far less extensive effort. In fact, with the aid of the namelist input the vegetation of the entire area could be input with one card if the user desired to specify a constant vegetation class for the area.

### 6.3 USER INPUT AND DATA BASE

Values corresponding to the variables of Tables 3-1 and 3-2 are presented in Figure 6.3. The data base in NAML1 consists of the first three pages of this Figure. The user inputs with the exception of the target data are in NAML2 which starts on the third page of Figure 6.3, while the target data (NAML3) starts on the seventh page of Figure 6.3. The user input for the sample case has been organized alphabetically so there is a one-to-one correspondence between this sample case and the inputs described in Section 3.0.

In order to exercise the dynamic route and external fire support options of the model, this sample case was organized as follows: For targets 1 and 2, the decision rule used was for SIAF to move toward these targets in an attempt to identify them. Once targets were identified, external fire support was to be called on the targets. For targets 3 and 4, the decision rule was to avoid these targets, if detected, by moving around them. For

targets 5 through 51, no dynamic movement was used. Instead, once detected, these targets were removed from the simulation and subsequent identification was not attempted.

#### 6.4 MODEL OUTPUTS

The outputs of the model consist of detail and summary printout. Detail printout presented in Figure 6.4 begins with some target transformations and then shows the X and Y coordinates of the SIAF location, the target currently being considered under the dynamic route option, and the current time in seconds. The second page of Figure 6.4, for example, indicates that IDTAR equals zero. Thus, there are no targets currently being considered for the dynamic route option at the simulation time shown. The third page of Figure 6.4 indicates that the dynamic route option was taken by the patrol at the time shown. Subsequent printout reveals that the patrol was moving toward the first target in an attempt to identify it. Finally, the fifth page of Figure 6.4 shows the result of an external fire support mission which was called on target number 2 and later on target number 1. This detail printout continues and presents a time history of a portion of the operation by showing when a dynamic route is used, the results of the external fire support missions, and the location of the patrol throughout the entire mission.

Summary printout of the simulation of the mission for all 51 targets is presented in Figure 6.5. Table 6-1 presents a brief description of these targets. For this summary printout, the dynamic route option described above was not used; hence, KREC(IT) was set equal to zero for all targets.

Included in Figure 6.5 are statistics pertaining to visual detection, target identification, aural detection, target location, movement, navigation, communications, supply maintenance, and human maintenance. As an example of the correlation of these results with the physical situation, Figures 6.6 and 6.7 are presented. Figure 6.6 shows the first six targets in the vicinity of the star cluster turn while Figure 6.7 shows the time line diagram associated with these targets.

A study of these Figures and Page 1 of the output data of Figure 6.5 reveals that for 5 replications, targets 1 through 3 were never visually detected by SIAF while targets 4 through 6 were always detected. Page 37

of the output reveals that the reasons for no detection on target 1 were primarily due to vegetation while targets 2 and 3 were always masked by relief. The aural detection statistics of Page 10 of Figure 6.5 indicate that targets 1, 2, and 5 were always detected by SIAF while target 4 (8 personnel) was not. Aural detection of target 3 and 6 was not feasible.

With respect to detections of SIAF, Page 19 of Figure 6.5 indicates that target 4 (8 personnel) visually detected SIAF once in 5 replications while Page 28 reveals no aural detections of SIAF by the enemy.

\* EVENTS PLANNED FOR A SECOND PATROL IN THE TEST, THAT PRESENT DETECTION OPPORTUNITIES FOR THE FIRST PATROL.

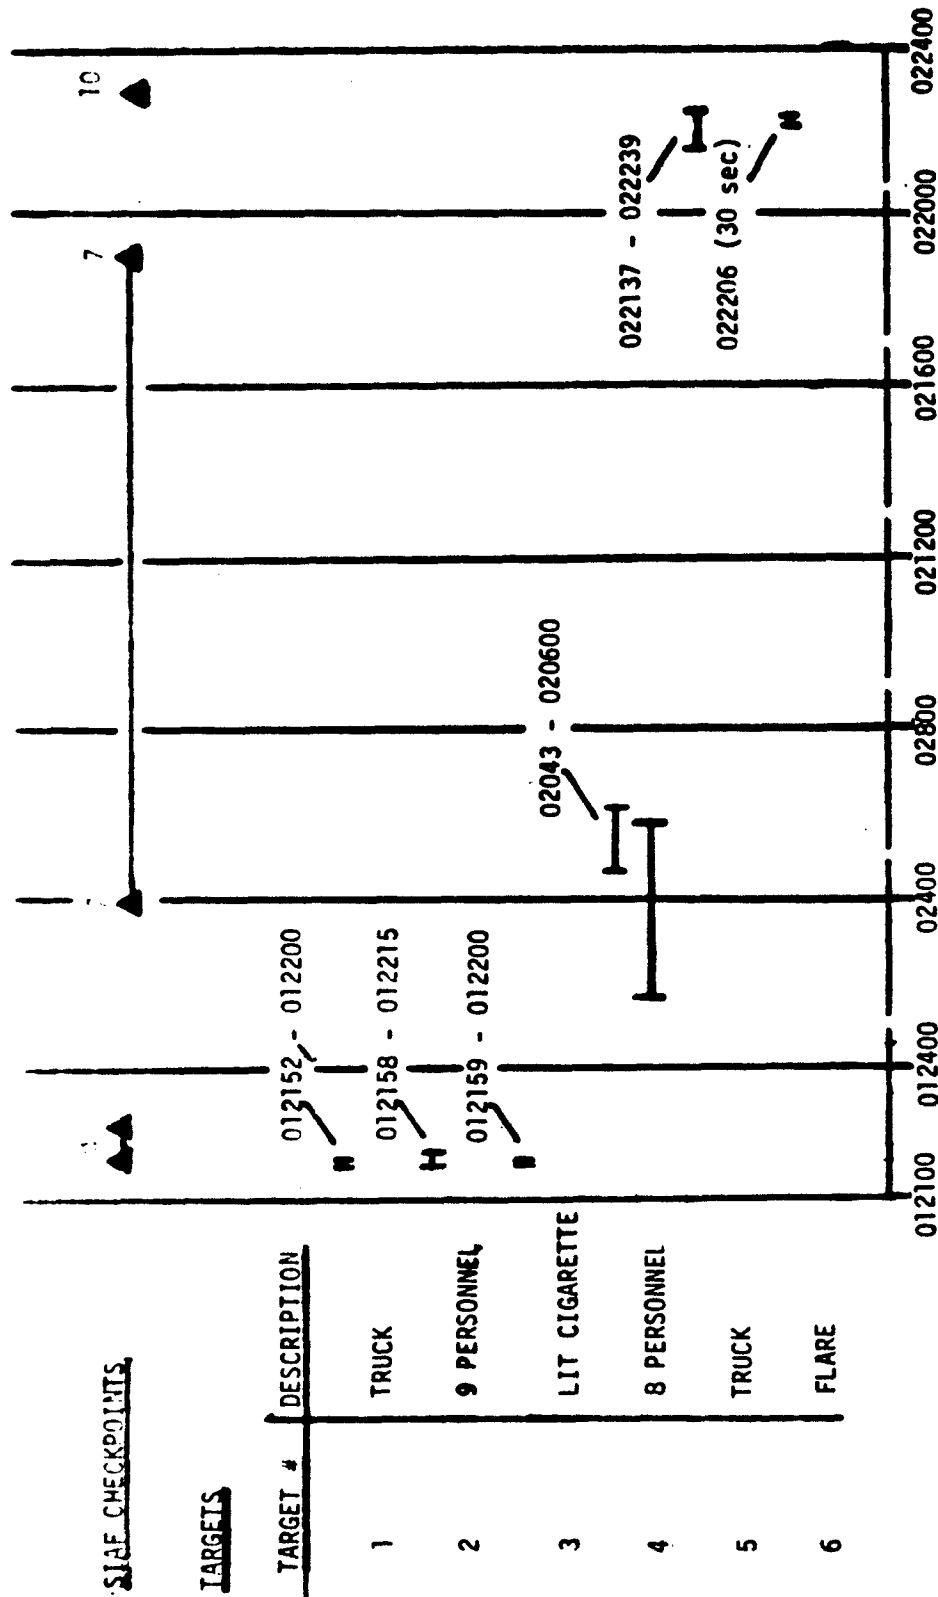

Figure 6.7, Timeline Diagram for Selected Portion of the Scenario

## 6.5 USER INPUT FOR THE COMBAT MODEL SAMPLE CASE

As an example of the operation of the integrated reconnaissance and combat model including the additions made in the modification contract, the following case is presented. Figure 6.8 shows the namelist input used for this case. The area of operations is taken from the Hunter Liggett Military Reservation. The scenario calls for a SIAF patrol of eight men on an ambush mission. They are moving in the dry El Piojo Creek bed at 0800. The scenario is diagrammed in Figure 6.9. The target starts on the other side of an 80 foot hill approximately 600 meters away. The target is a six-man patrol and is heading on a collision course with the SIAF.

## 6.6 OUTPUTS FOR THE COMBAT MODEL SAMPLE CASE

The outputs of the model, shown in Figure 6.10, consist of detail and summary printout. The detailed printout begins with the location of the target and of the SIAF. Two lines of printout are generated by the Reconnaissance model at the end of each segment. This gives the positions, a detection verdict, the time, and the reason for no line of sight.

At 17 minutes into the mission, the SIAF detects the target. This is shown by point 1 on Figure 6.9. It is in an area of both vegetation and microrelief. The output then shows the generation of a dynamic route to seek recognition of the target. The grid plot shows the selected grid points for the dynamic route. One minute later, the SIAF identifies the target. The range is 264 meters. This is shown by point 2 on Figure 6.9 for both the SIAF and target. At this point, a dynamic route is generated to return to the original route should that be the decision of the SIAF.

The action selected by the decision logic submodel is to continue to ambush. A preliminary deployment point and engagement point is selected which is the first admissible point. The optimization logic then selects deployment points for both a base of fire and a moving maneuver unit. These are shown by the pair of points labelled number 3 at the edge of the wooded area. The projected engagement point for the target is also shown. The optimization logic also determines an assault point close to the target.

At this point in the simulation, the terrain resolution is shifted from 50.8 meters to 12.7 meters for greater accuracy in the line of sight calculations. The individual attributes are then printed for both patrols

at the start of combat. The next computation is the generation of dynamic routes for the attacker maneuver units to the deployment points.

The combat model through its executive routine, CMAIN, then assumes control of the simulation. This is driven by the first occurrence of a detection, arrival at the checkpoint (generated by dynamic route routine), casualty, or 20 seconds if nothing else happens. For other missions, it considers also the arrival of an external fire support burst and the detonation of Claymore mines. For this case, the first few events are individual detections by SIAF members of target members. More detections could be occurring, but only one is printed per patrol at each event interval. Here the locations of the maneuver unit leaders are also printed. The next two events are arrivals at the intermediate dynamic route points. This process continues until both maneuver units have arrived at their deployment points. At this time, they stop. A dynamic route is generated for the moving maneuver unit to get to the assault point, but movement does not begin on this leg for an ambush until the firefight has begun. The model continues to print detection events for the attacker of the defender while the defender is moving to the engagement point.

When the defender arrives at the engagement point, the SIAF opens fire and a casualty event occurs within 2 seconds. As shown in the printout, the casualty is defender number 5 who sustains a minor wound. The next event is another casualty. This time defender 2 sustains a major wound. The elapsed time of the firefight is 3.3 seconds. The attribute tables for both patrols are then printed as they are after either a major wound or death. At this time, the defender decides to withdraw and selects a direction 180° opposite to which it was moving. The break decision was due to the high number of casualties.

At the five second point, defender number 3 is killed. The break decision printout is repeated for information purposes, but no new action is taken. The next event is a major wound for defender 1 at 6.2 seconds. At 7.8 seconds, defender 6 is killed and at 9.7 seconds, defender 4 is killed. At this point all defenders have been killed or wounded. The SIAF stops firing and the moving maneuver unit reaches the first checkpoint on its assault route.

At 30 seconds, however, the SIAF decides to break due to an elapsed time criterion. A rally point is selected on the opposite side of the hill and the SIAF begins moving. After arriving at the rally point, the patrol decides to continue the reconnaissance mission. The final attributes are printed and control is returned to the Reconnaissance Model. At this time, the elevation data at the 50.8 meter resolution is retrieved. The SIAF then completes its operations plan and is extracted. Summary statistics for the mission are then printed.

#### 6.7 EXAMPLE USING EXTERNAL FIRE SUPPORT

The same case was run using external fire support in preparation for the firefight. The same inputs were used except the mission was changed to attack. The same deployment and engagement points were selected, but this time a volley of artillery shells arrived soon after the request. Figure 6.12 shows the detailed output from there on. First the burst points are printed and then the attributes after the burst. The next event is a casualty inflicted by the SIAF who open fire after the first volley. The next events are arrivals of more volleys of artillery. Again the target decides to break in the opposite direction. The attacker decides to break due to the elapsed time criterion.

#### 6.8 EXAMPLE USING CLAYMORE MINES

For this case, the mission was switched to an ambush using Claymore mines. As shown in Figure 6.13, the mines were deployed just inside the edge of the wooded area. The SIAF was deployed in the woods and was not detected by the target. When the target reached the most vulnerable area with respect to the mines, they were detonated and all of the target personnel were killed. Control then returned to the Reconnaissance model after the withdrawal. The detailed output is shown in Figure 6.14.

1 8 24 30 1470.96 1648.66 MOVEMENT ATTACKER MU 1 WILL MOVE 10.08 METERS AT AN ANGLE OF --  
1 8 24 30 1465.91 1649.38 MOVEMENT ATTACKER MU 2 WILL MOVE 10.08 METERS AT AN ANGLE OF --  
RESOLUTION HAS BEEN CHANGED BACK TO THE RECONNAISSANCE LEVEL OF 50.8 METERS

DECISION ON CONTINUATION OF RECONNAISSANCE MISSION AFTER COMBAT OPERATION IS COMPLETED :

MISSION DECISION : CONTINUE

CURRENT AMOUNT OF FOOD REMAINING PER MAN(LB.) : 13.4442

CURRENT AMOUNT OF WATER REMAINING PER MAN(LB.) : 6.9334

PATROL DURATION (DAYS) : 1

STAF DETECTS TARGET NO. 1 VISUALLY

STAF RECOGNIZED TARGET NO. 1 AT X- 1470.96 Y- 1648.66 THE RECOGNITION RANGE IS 543.21

## 7.0 OPERATING PROCEDURES

This section describes the operating procedures in terms of hardware requirements, software requirements, overlay structure of the model, and sample deck setup.

### 7.1 HARDWARE REQUIREMENTS

- CDC 6000 series digital computer
- SCOPE operating system
- FORTRAN EXTENDED source program compiler (FTN)
- COMPASS assembler
- Tape drive for input of topocom tape
- 232K of octal 60-bit words central memory
- Temporary and short-term storage devices (i.e., disk or tape)
- Standard system file configuration for input data and object program modules.

### 7.2 SOFTWARE REQUIREMENTS

- FORTRAN unit 1 is used for reading namelist input data. This data consists of NAML1, NAML2, NAML3, and NAML4. File NLINP is referenced to this unit.
- FORTRAN unit 2 is used for temporary storage. At the beginning of the model the packed reconnaissance elevations are stored here. After the return of a combat operation this unit is read to restore reconnaissance elevation data. File PAKZ is referenced to this unit.
- FORTRAN unit 5 is used for standard input. File INPUT is referenced to this unit.
- FORTRAN unit 6 is used for standard output. File OUTPUT is referenced to this unit.
- FORTRAN unit 7 is used for temporary storage. When a start/stop point is reached, the common blocks are dumped or read from this unit, so that the model can be started or stopped at specific points. File START is referenced to this unit.
- FORTRAN unit 8 is used for reading elevation input data. This file is a direct output of topocom programs, MAPGEN or ROTATE. File ZINP is referenced to this unit.

- FORTRAN unit 9 is used for intermediate storage. The common block **STATS** is updated on this unit for each replication of the model. File **STATS** is referenced to this unit.
- Most of the **COMMON** blocks used by the **SIAF** program are defined in the following computer pages 1 through 47 of Figure 7.1. These blocks were generated by the **BLKGEN** program described in Appendix A of this volume. Using these **COMMON** blocks the **SPECPL** program defined in Appendix B of this volume, punched out the **DIMENSION** and **EQUIVALENCE** statements for all subroutines requiring any variable pertaining to the **COMMON** blocks.
- To facilitate finding a location of a common variable, Figure 7.2 gives an alphabetical list of all variables in these commons. Furthermore, their location in that block and the block name are given along with its dimension if the variable is an array.

### 7.3 OVERLAY STRUCTURE

- Figure 7.3 is a chart overview of the overlay structure organization. Within each overlay block the overlay level is given and the sub-routine and programs are listed alphabetically, along with the size of the model with that overlay.

### 7.4 SAMPLE DECK SET-UPS

- Figures 7.4 - 7.6 are listings of card decks that would be required to create the model from tape starting from scratch and end up with an execution of the sample case.
- Figure 7.4, when submitted, will create or copy from the **SIAF** tape, all source cards and store them on permanent disk files.
- Now, execution of Figure 7.5 will compile all these source cards and create the object modules required for loading. These also are stored on permanent disk files.
- Figure 7.6 takes the generated object modules along with the required input files and executes the sample case.

Revised December 1973

## 7.5 INSTALLATION

- The SIAF program as described above was installed and runs on a CDC 6500 digital computer at the USACDC Data Processing Installation, at Fort Leavenworth, Kansas.

## 8.0 SIAF RELIEF MODEL VALIDATION

### 8.1 PURPOSE

The purpose of this discussion is to describe the method and results of simulating line of sight experiments to demonstrate the validity of: 1) the line of sight calculations; and 2) the mathematical concept of macro-relief representation in the SIAF Terrain Submodel. The raw data used in the simulation was taken from field measurements at nine different locations in the Hunter-Liggett Military Reservation. The experiment measures line of sight data with respect to macro-relief only; the effects due to vegetation and micro-relief features are neglected.

### 8.2 HUNTER-LIGGETT FIELD EXPERIMENT

#### 8.2.1 Purpose

The primary purpose of the field experiment was to gather actual line of sight data concerning terrain macro-relief. The line of sight experiments were conducted at nine locations within the map section shown in Figure 8.1.

#### 8.2.2 Equipment

The experiments required three pieces of equipment. A compass was used to determine direction, a one-hundred meter rope, graduated in five meter intervals was used to measure surface distance, and a pair of walkie-talkies was used to relay information.

#### 8.2.3 Methodology:

The typical procedure undertaken is depicted in Figure 8.2. An observer would stand at an easily identifiable point (i.e., landmarks, roads, peaks, saddlepoints, etc.) with a compass and walkie-talkie. One end of the hundred-meter rope is held by the observer. Another individual, designated as the "target", moves away from the observer holding the other end of the rope. The target is also equipped with a walkie-talkie. The target continues to walk away from the stationary observer, until only the target's head is visible (to the observer) due to the interruption of the line of sight by the ground. The observer and target are in radio communication, so that the location of the target at the time of line of sight interruption is established accurately.

Page 8-3

Revised December 1973

Figure 8.2, LOS Experimental Procedure

The procedure was repeated at approximately every fifteen degrees of arc, at which time a third individual would record the heading, and the "surface distance" between the observer and target. By "surface distance" we mean the distance traced out by the rope over the curvature of the ground. This is to be distinguished from the "range distance," which is the distance between observer and target when the line of sight is projected onto the grid plane of zero altitude. See Figure 8.3 for the distinction. This procedure continued over a three hundred and sixty degree sweep about the observer, whenever the terrain permitted.

Line of sight data was collected at nine different locations. At each site, several direction headings and the corresponding surface distances were recorded. The nine locations are shown in Figure 8.1, and the experimental data is displayed in Figure 8.4.

#### 8.2.4 Field Measurement Errors

In conducting an experiment of this type, four sources of error are inherent and must be taken into consideration using the data for validation purposes.

- Location Error: Exact determination of the observer's position (grid coordinates) is impossible. Minimizing the effects of this type of error was achieved basically by choosing observer positions near relief landmarks such as roads, peaks, saddle-points, and intersections.
- Compass Error: Compass readings are subject to errors due to alignment, sighting, and reading errors. An additional error source is in the estimation of magnetic north with respect to grid north. It is estimated that the combined effects of such errors amounts to  $\pm 2^{\circ}$  error.
- Linear Measurement Error: All distances recorded on a map are given for a grid plane (of zero altitude) normal to any given elevation. The experiment, however, was conducted around sloping, hilly areas. Thus, the measured distance between the observer and target is the sloping surface ("slant") distance, and will be in error as a function of the distance and the difference in elevation between them. An approximation

Figure 8.4, Field Data (Hunter Liggett)

of this type of error is given by  $D_E = D_M - D_M \cos(\theta)$ , where  $D_E$  is the error in the distance measurement,  $D_M$  is the actual measured distance, and  $\theta$  is the angle of elevation between observer and the target.

- Vegetation: As stated earlier, the intent of the experiment was to validate the SIAF model using line of sight verdicts with respect to macro-relief only. The effects of vegetation on line of sight were ignored. However, the presence of grass, sometimes several feet in height, could have introduced error into the measurements. This type of error is dependent on the density and height of the grass. The distance at which the line of sight is lost tends to be less in the presence of grass than otherwise. The effect of this error was minimized by choosing observer locations having very little vegetation (grass having negligible height) whenever possible.

### 8.3 ELEMENTS OF SIAF MODEL USED IN VALIDATION

#### 8.3.1 Mathematical Representation at Macro-Relief in SIAF Model

The SIAF model utilizes a grid concept to describe macro-relief. Within each grid square a continuous surface is mathematically represented by a quadratic surface weighting all four corner elevation points. A region under consideration is assumed to be sufficiently small, so that effects due to earth's curvature are neglected, (i.e., a flat earth assumption is made, allowing use to use surface altitudes given by topographical maps). At each grid point, the earth's surface is specified by its altitude. Altitude data is available for grid resolutions as fine as 12.7 meters. The surface at nongrid points are determined as a weighted average of the four altitudes at the corner points of the grid square in which the point lies.

Consider Figure 8.5. Grid lines are defined by

$$\begin{aligned}x_j &= (j-1)\Delta x \\ y_k &= (k-1)\Delta y\end{aligned}$$

where  $\Delta x$  and  $\Delta y$  are grid square dimensions. The  $j, k^{\text{th}}$  rectangle is bounded by the grid lines  $\{x=x_j, y=y_k, x=x_{j+1}, y=y_{k+1}\}$ . The surface within the  $j, k^{\text{th}}$  grid square, as shown in Figure 8.5, is determined in the following manner where  $z_{j,k}$ ,  $z_{j,k+1}$ ,  $z_{j+1,k}$  and  $z_{j+1,k+1}$  are the input

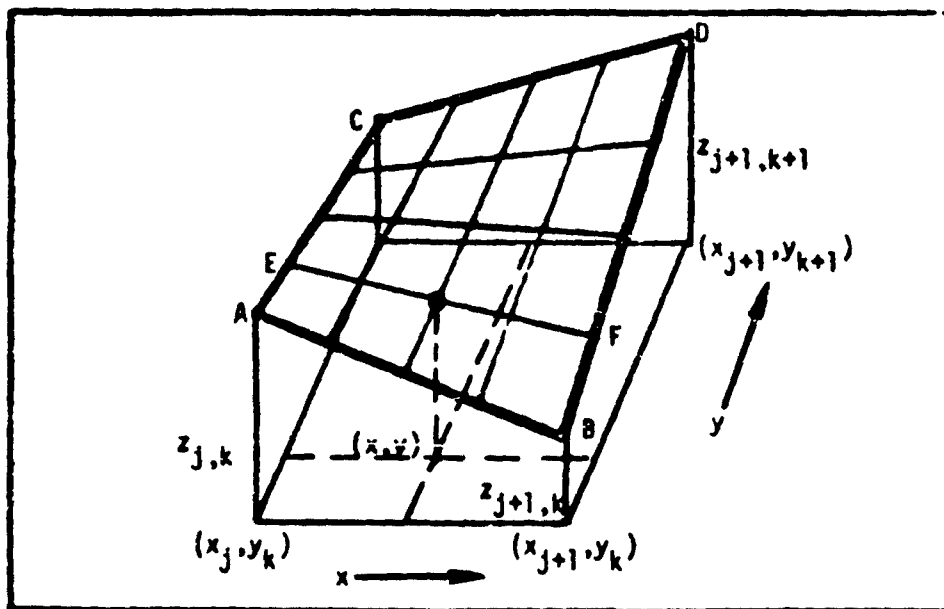

Figure 8.5, Surface Within  $j, k^{\text{th}}$  Rectangle

altitudes of the four corner points:

$$\text{Altitude on Line AB: } z_k(x) = \left[ z_{j,k} + \frac{x-x_j}{x_{j+1}-x_j} (z_{j+1,k} - z_{j,k}) \right]$$

$$\text{Altitude on Line CD: } z_{k+1}(x) = \left[ z_{j,k+1} + \frac{x-x_j}{x_{j+1}-x_j} (z_{j+1,k+1} - z_{j,k+1}) \right]$$

Altitude on Line EF (weighted average):

$$z(x,y) = \left\{ z_k(x) + \frac{y-y_k}{y_{k+1}-y_k} [z_{k+1}(x) - z_k(x)] \right\}$$

### 8.3.2 SIAF Subroutines Used

The subroutine LOSVEG is responsible for the line of sight calculations in the SIAF model. This subroutine is called by the subroutine DETERR. DETERR calculates intervisibility between any pair of points on the terrain for prone and upright positions of both the observer and the target. This intervisibility is characterized in terms of line of sight obstructions and various probabilities of cover and concealment. Cover and concealment are provided by micro-relief features and vegetation. Since the purpose of the field experiment was to consider macro-relief only, the line of sight experiments were performed in areas characterized by little or negligible amounts of micro-relief objects and vegetation. Thus the effects of cover and concealment on intervisibility are neglected in the simulation, and DETERR was modified to do this. Furthermore, for each pair of points on the terrain locating the observer and target, four lines of sight are considered by the subroutine DETERR.

- 1) "Head to head", i.e., observer and observed both upright.
- 2) "Head to foot", i.e., observer upright and observed prone.
- 3) "Foot to head", i.e., observer prone and observed upright.
- 4) "Foot to foot", i.e., observer and observed both prone.

Since the field experiments considered only "head to head" lines of sight, DETERR was modified such that the simulation considered only that case.

The primary purpose of LOSVEG is to determine if the line of sight between an observer and target is obstructed by the intervening land surface (macro-relief). It accomplishes this by projecting the line of sight onto a grid plane (of zero altitude). Every intersection of the line of sight with horizontal and vertical grid crossings partitions the line of sight into segments. The subroutine checks for line of sight interruptions within or at the end-point of a given segment. This is done segment by segment, beginning with the segment containing the observer's position, until the line of sight is interrupted. If no interruption occurs the fraction of target height and the fraction of observer height covered by macro-relief is calculated; the routine continues on to compute cumulative distance through vegetation. It checks to see whether the cumulative distances through certain vegetation feature types is great enough to cause concealment of the target. This cumulative vegetation check, however, is of no concern to this test.

Detailed documentation and flow charts of LOSVEG and DETERR can be found in Volumes II and V respectively of the SIAF Users Manual.

#### 8.4 COMPUTER SIMULATION OF FIELD TEST

The subroutines discussed above were modified and inserted into a program designed to simulate the line of sight experiments conducted at Hunter Liggett. The program considers only macro-relief features; it also takes into account several of the error sources which were inherent in the field experiments.

##### 8.4.1 Simulation Methodology

The basic simulation procedure tries to model the actual experimental procedure conducted in the field. A given observer's position (grid coordinates on a topographic map) is determined as accurately as possible. Based on this determination, the program reads in all the elevation data in a square area centered about this point. The area is 444.5 grid points (using 12.7 meter resolution).

As in the actual experiments, the target is programmed to move away from the observer in a fixed direction. The target steps off increments of 3.175 meters away from observer. Every step increment initiates a call to subroutine DETERR, which in turn, calls LOSVEG to determine if a "head-to-head" line of sight exists. If it does the target takes another step of 3.175 meters away from the observer. The line of sight routine is called again. The procedure is repeated as long as the line of sight exists. This continues until either the line of sight no longer exists due to macro-relief obstruction, or the target has stepped off so many increments away from the observer that elevation data is no longer available for line of sight calculations. In the latter case, the distance between the observer and the target for which line of sight remains uninterrupted by macro-relief is considered to be unlimited.

Once the line of sight is obstructed, the target is programmed to move towards the observer. The step increment is reduced by half to 1.5875 meters. Again, each step increment initiates a call to the appropriate subroutines giving a line of sight verdict. The target is programmed to continue the inward movement until an uninterrupted line of sight is established again. As soon as the line of sight has been re-established, the target begins moving away from the observer once more. Now the step increments are made smaller ( $1.5875 \div 2$ ). As before, each step gives rise to a line of sight verdict. The target continues moving away from the observer until the line of sight is interrupted by macro-relief again. At this instance, the range between the observer and target is recorded. In addition, the ranges between the observer and the line of sight intersections with grid crossings are recorded. These distances are needed to form an approximation of the actual surface between the observer and target. In short the simulation obtains data to approximate the surface distance by pinpointing the target's exact location (in a forward and backward manner) at the instant of line of sight obstruction.

The surface distance approximation is required because LOSVEG projects all lines of sight onto a grid plane of zero altitude, and computes all distances on this plane. Naturally, for extremely undulating relief, the linear range computed would be a poor approximation of the actual surface

distance measured at Hunter Liggett. Figure 8.6 illustrates the estimation procedure. The distance between two successive grid crossings is computed. This is done for the  $C^{\text{th}}$  grid line by subtracting  $D(C)$  from  $D(C+1)$ . The elevations at points where the line of sight intersect the two grid crossings are computed also ( $ZZZ(C+1)$ , and  $ZZZ(C)$ ). The difference in elevation at these two points can be computed by subtracting  $ZZZ(C)$  from  $ZZZ(C+1)$ . The surface distance from the  $C^{\text{th}}$  line is the length of the hypotenuse of the right triangle having sides  $|D(C+1)-D(C)|$  and  $|ZZZ(C+1)-ZZZ(C)|$ . The estimation procedure is repeated for all grid squares having intersections with the line of sight; the results are summed to produce the surface distance from observer to target.

#### 8.4.2 A Measure for Evaluating Validity

A comparison is made between the actual surface distance measured in the field and the estimated surface distance produced by the simulation. The absolute value of the difference between the actual and simulated surface distances is computed. This difference provides a measure for evaluating the credibility of:

- 1) the line of sight calculations and
- 2) the mathematical representation of macro-relief.

Specifically, a difference that approaches zero indicates that the simulation is producing reasonable results. However, a very small difference, or a difference of zero should not be interpreted as evidence of complete validity. It merely reflects that the line of sight algorithm, and the mathematical model for relief give reasonable estimates of the true situation.

#### 8.4.3 Error Adjustments

Recall that the raw data from the field experiments was subject to four basic types of error. One such error involved inaccuracies in pin-pointing the exact location of the observer on a topographical map. A pencil point on a map of scale 1:50000, can be in error by as much as 20 meters. Furthermore, the exact location of the target is in doubt, not only due to the uncertainties in the observer's location, but due to

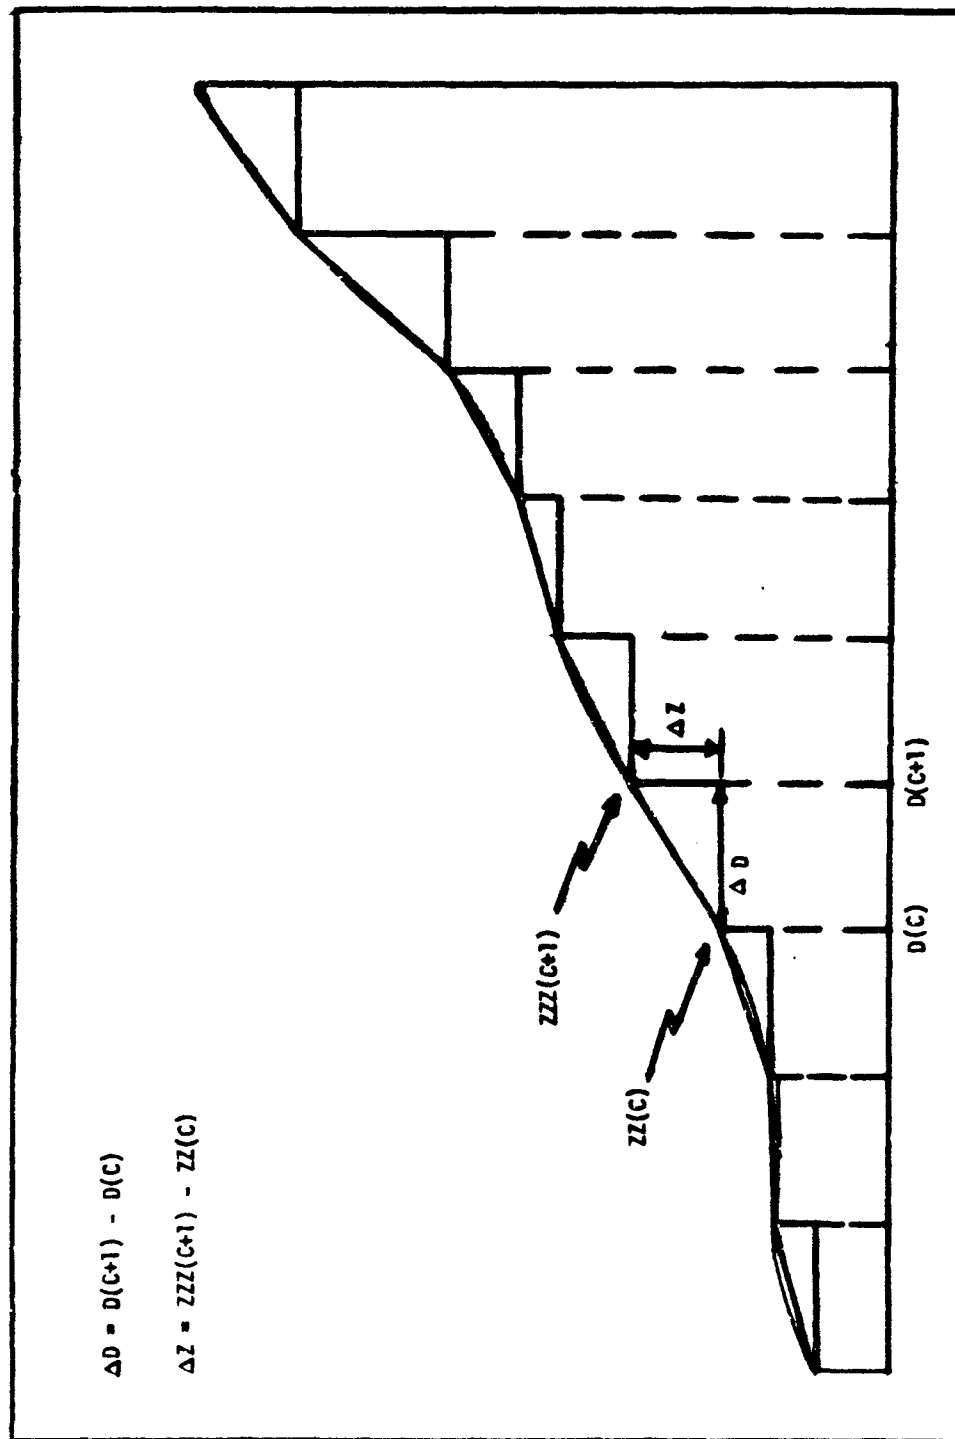

Figure 8.6 ESTIMATION OF SURFACE DISTANCE

compass errors. The computer simulation attempts to correct such errors by:

- 1) considering a set of observer locations; and
- 2) slightly perturbing the angle of direction which locates the target relative to the observer.

Instead of investigating one possible observer location, the simulation considers a set of possible locations. Thirty-six equally spaced points within a 12.7 by 12.7 square area are analyzed. Each point is 2.54 meters apart. Thus, the input for "observer location" is not given by a pair of coordinates denoting a single point; it is given by a small grid area enclosing the most likely observer location. See Figure 8.7. This technique removes the guesswork involved with measuring map coordinates (by hand with a ruler), and places more emphasis on locating the observer's position relative to his immediate macro-relief environment.

At every observer location at Hunter Liggett, line of sight data was gathered in several different directions. The recorded angle (relative to magnetic north), for a given direction will be designated the "base angle." This angle contains small uncertainties due to compass reading errors. The simulation attempts to eliminate these uncertainties by perturbing the base angle slightly ( $\pm 1^\circ$  and  $\pm 2^\circ$ ). Thus, five different line of sight determinations are performed for a given direction:

- 1) the base angle determination;
- 2) base angle  $+2^\circ$ ;
- 3) base angle  $+1^\circ$ ;
- 4) base angle  $-1^\circ$ ; and
- 5) base angle  $-2^\circ$ .

In each case, the absolute value of the difference between actual and simulated surface distance is computed. The angle resulting in the smallest difference is chosen as the new "base angle" for that given direction. The same procedure is applied to each of the several other directions recorded at the experiment site.

In most instances, the simulation examined only three recorded directions at each experiment site. These three directions were chosen arbitrarily, but remained the same for each of the thirty-six points at

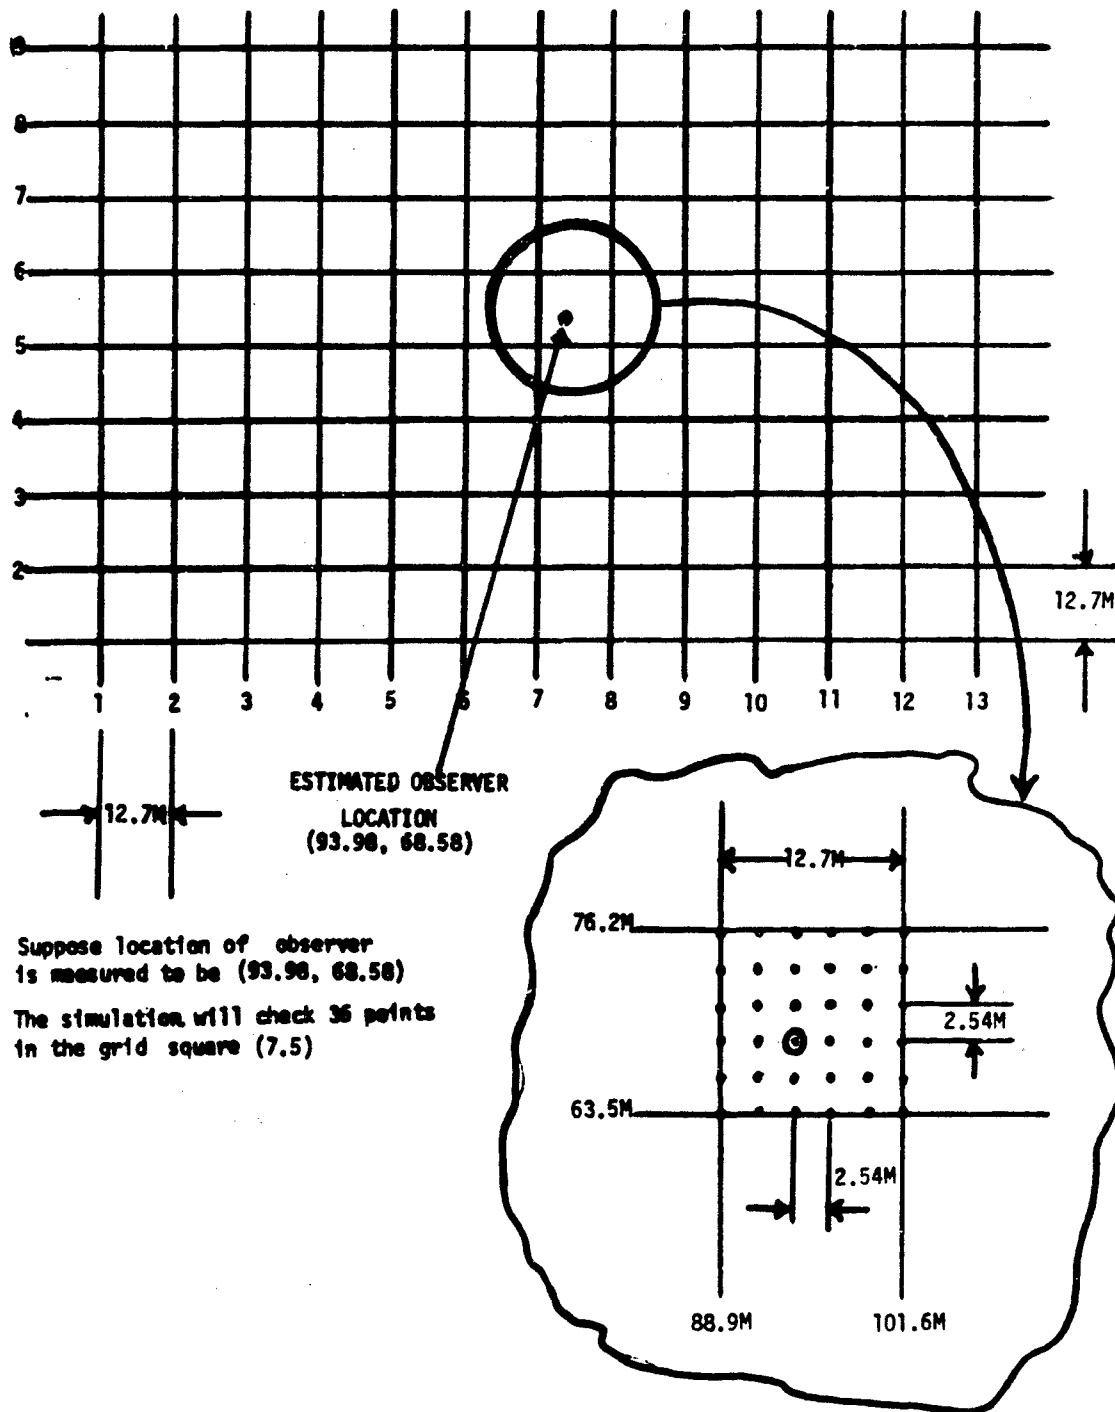

Figure 8.7 GRID OR OBSERVER LOCATION

a given location. Computer costs involved with examining more than three directions were prohibitive: the simulation considers thirty-six points. If three directions are examined, then fifteen line of sight experiments are performed (3x5). Thus there are 36x15=360 line of sight experiments performed for one location at Hunter Liggett.

#### 8.4.4 Overall Measure of Validity

Recall that the absolute difference provided a measure of validity for a line of sight experiment conducted in one direction. But for each point, three different directions were analyzed. Thus a summary statistic, measuring the accuracy of line of sight calculations for all three directions, was needed.

The root mean square of the difference in each direction was chosen to measure the accuracy of all line of sight calculations at a given point. Specifically, the quantity measuring overall validity for line of sight calculations in all directions is given by:

$$\sqrt{\frac{\sum_{I=1}^N \{D_A(I) - D_C(I)\}^2}{N}}, \text{ where } D_A(I) \text{ is the actual}$$

surface distance in the  $I^{\text{th}}$  direction,  $D_C(I)$  is calculated surface distance in the  $I^{\text{th}}$  direction, and  $N$  is the number of directions analyzed ( $N=3$  in this simulation). Thus every one of the thirty-six possible points under consideration has associated with it, a root mean square difference. This number reflects the accuracy of the simulation experiments at each of these points. The location of the point having the least root mean square difference is chosen to represent the actual position of the observer in the field experiment.

#### 8.4.5 Simulation Using Different Resolutions

The simulations were conducted using three grid size resolutions. The initial simulation was done with elevation data available at grid points 12.7 meters apart. This was the finest resolution of elevation data available; hence this resolution was used to locate the actual

positions of the observer at the experiment sites. Having established these locations, the simulation was performed using coarser resolution: elevation data points 25.4 and 50.8 meters apart respectively. The simulation procedure using cruder resolution is exactly the same as described above, except that it no longer examines the set of thirty-six possible points for an actual location (it uses the actual locations derived from the initial simulation, thus avoiding a great deal of processing).

#### 8.5 ANALYSIS OF SIMULATION RESULTS.

The root mean square (of differences between actual and simulated surface distance in all line of sight directions examined for a given experiment site at Hunter Liggett) provides a measure for evaluating the validity of the line of sight routines and macro-relief representation. Figure 8.8 gives these measures for all nine Hunter Liggett experiment sites, at the various resolutions used in the simulation. Figure 8.9 presents the simulation results broken down into individual line of sight experiments. The overall root mean square difference is given on this figure also.

As Figure 8.8 indicates, the simulation performed under 12.7 meter resolution produce very credible results. The results using 25.4 and 50.8 meter resolution are credible, but not as sharp. The reason for this is that the line of sight interruption distances measured are relatively short (i.e., with respect to the length of the side of the grid squares). Many of the line of sight obstruction distances measured at Hunter Liggett were less than 100 meters in length. These short distances do not affect the simulation when the resolution is very fine (i.e., 12.7 meter resolution), but as the resolution becomes coarser, the simulation results are more inaccurate. It must be stressed that this happens only when simulation is attempted over very short lines of sight using very coarse resolution. The inaccuracies appear in the form of large root mean square differences. Coarse resolution should be used in line of sight determinations when the observer and target are over 200 meters away.

| SITE | 12.7 METERS RESOLUTION |         | 25.4 METERS RESOLUTION |         | 50.8 METERS RESOLUTION |         |

Best Available Copy

Figure 8.10 demonstrates what can happen when line of sight calculations are conducted over a short distance using various resolutions. An observer and target, both of height 1.8 meters, stand 12 meters apart. Macro-relief described with 12.7 meter resolution indicates a line of sight interruption at approximately 6.7 meters from the observer. However, no such line of sight interruption occurs when describing macro-relief with 25.4 or 50.8 meter resolution. The figure shows that the hump at about 6.7 meters from the observer is not modeled when describing macro-relief using the cruder resolutions. This explains why some of the root mean square differences are so large when the simulation was run using 25.4 and 50.8 resolution (recall that the target keeps moving away from the observer until a verdict of obstruction is given).

The simulation results particularly those obtained when using the 12.7 meter resolution demonstrate that the SIAF line of sight routine and the SIAF representation of macro-relief are "reasonable". Furthermore, line of sight calculations are sensitive to resolution when the distance between observer and target is small (i.e., less than 100 meters). For the reason, the SIAF concept of switching resolution (using less resolution in the Reconnaissance Mode when long distances are involved; and finer resolution in the Combat Mode when shorter distances are involved, and more detailed computation are required) appears well founded.

#### 8.6 SUMMARY

Line of sight data was collected at nine different locations at the Hunter Liggett Military Reservation. At each location, line of sight experiments were conducted in several different directions. Inherent errors in compass reading and in locating positions on a topographical map required the simulation to consider a set of possible locations and to vary the directions between observer and target. The initial simulation examines a set of thirty-six equally spaced (2.54 meters apart) points enclosed in a 12.7 by 12.7 meter grid square. Each of the thirty-six points are analyzed as follows. Three arbitrary experimental directions were chosen. Each direction is perturbed by  $\pm 1^\circ$  and  $\pm 2^\circ$ , so that five line of sight verdicts are obtained. The verdict which offers the minimum

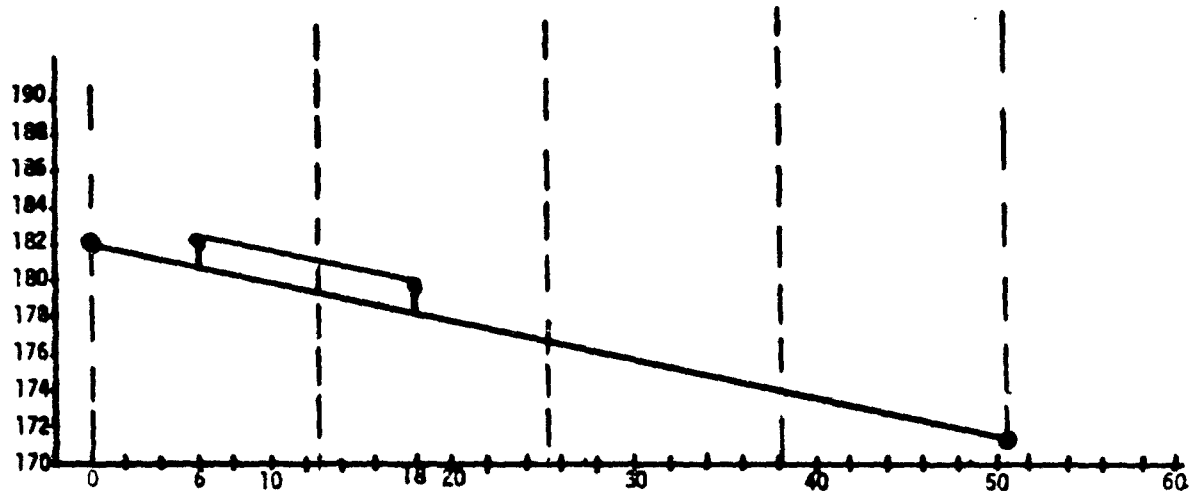

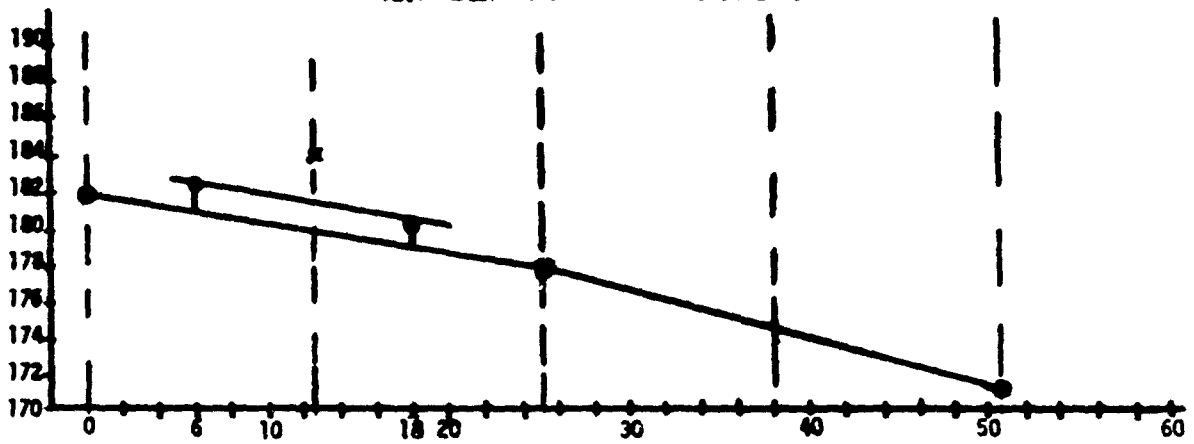

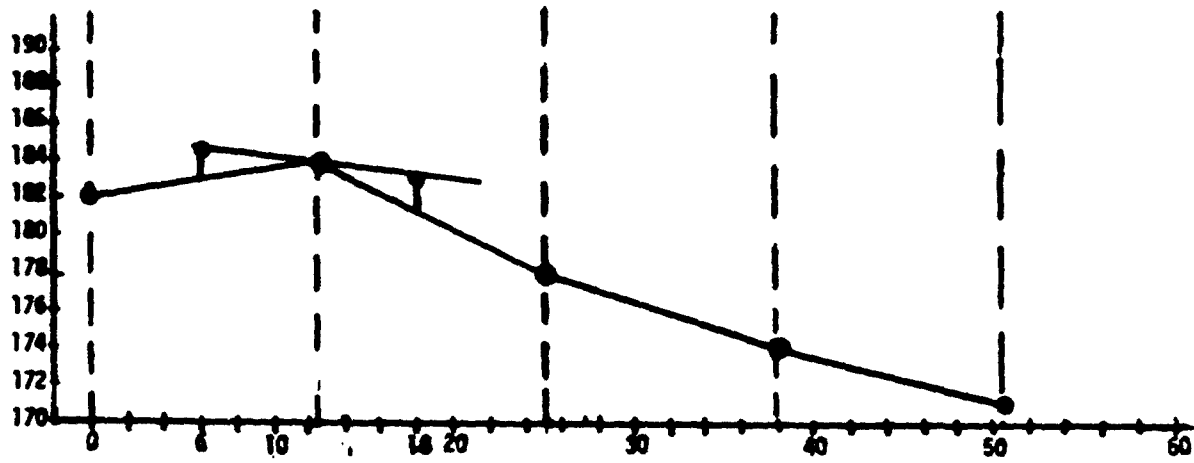

Figure 8.10 LOS VERDICT USING DIFFERENT RESOLUTIONS

difference between actual and computed surface distance determines the base angle for that direction. Thus each direction has associated with it, a measure of how accurate the simulation was. The root mean square of these individual differences gives an over measure of how accurate the simulation of the field experiment was at that point. The root mean square difference is given by:

$$\sqrt{\frac{\sum_{I=1}^N \{D_A(I) - D_C(I)\}^2}{N}}$$

where  $D_A(I)$  is the actual surface distance,  $D_C(I)$  is the computed surface distance, and  $N$  is the number of directions analyzed.

The initial simulation examines thirty-six possible points for a given experiment location, thus producing thirty-six root mean square differences. The location of the point having smallest root mean square is considered the site where the line of sight experiment actually took place. All nine experiment sites at Hunter Liggett were determined by the above procedure.

The simulation was repeated using resolutions of 25.4 and 50.8 meters. The same procedure was applied, except the observer positions are inputted (from initial simulation) instead of calculated.

The results of the simulation demonstrate that the SIAF line of sight calculations and the SIAF model of macro-relief are valid. Also, when the distance between observer and target is small (i.e., less than 100 meters), the line of sight calculations are dependent on resolution.

#### 8.7 COMPARISON WITH ASARS BATTLE MODEL

Macro-relief models usually employ a grid square concept in which elevation data is known at four corners of each grid. The elevation at points lying between these data points are represented by an interpolated value using the known data points. Different methods are used to obtain these interpolated values. As mentioned before, the STAF model uses a continuous

surface representation within a grid square based on the four surrounding grid points. A less complex method uses two intersecting triangular planes within a grid square to obtain interpolated values. This scheme is used in the ASARS model. The simulation experiment was done utilizing both representations of macro-relief; the results were compared.

#### 8.7.1 ASARS Methodology

ASARS macro-relief is modeled by specifying two triangular planes within a grid square. The planes are defined by specifying a diagonal within the grid square (a positive diagonal if it connects the lower left corner with the upper right corner; a negative diagonal if it connects the upper left corner with the lower right corner). The orientation of the diagonal is the same for all grid squares under consideration. Positive diagonals were used in the simulation.

The line of sight subroutine in the ASARS model is basically a series of comparisons. The line of sight between the observer and the target is projected onto a grid plane (of zero altitude) and partitioned into a set of segments. The endpoints of these segments are defined by the intersection of the line of sight with horizontal and vertical grid crossings and with diagonals. Initially, the horizontal distance between observer and target, and the vertical difference in elevation between the top of the observer and the top of the target are computed. These quantities are used to compute the tangent of the angle subtended by the line of sight and a horizontal line parallel to the grid plane at the top of the observer. This tangent value is designated "TANLIM".

The line of sight routine proceeds as follows: the elevation of the ground surface at an endpoint of a segment is referenced. The horizontal range from the observer to the endpoint is computed. These quantities are used to compute the tangent of the angle subtended by the line extending from the top of the observer to the ground surface at that endpoint, and the horizontal line parallel to the grid plane at the observer's height. Call this quantity "TAN". Figure 8.12 illustrates the above procedure. A comparison is made between TANLIM and TAN, to determine the line of sight verdict: If TAN is greater than or equal to TANLIM, the line of sight is interrupted at that endpoint. Otherwise, the line of sight exists and the

\* UNLIMITED LINE OF SIGHT (i.e., TARGET HAS STEPPED OFF SO MANY INCREMENTS FROM OBSERVER THAT ELEVATION DATA IS NO LONGER AVAILABLE FOR LOS CALCULATIONS).  
FIGURE 8.10 ILLUSTRATES HOW THIS CAN HAPPEN.

ERROR =  $D_C(U) - D_A(I)$  WHERE  $D_C(I)$  IS THE CALCULATED SURFACE DISTANCE IN THE  $I^{TH}$  DIRECTION AND  $D_A(I)$  IS THE ACTUAL MEASURED SURFACE DISTANCE IN THE  $I^{TH}$  DIRECTION

FIGURE 8.11 STAF AND ASARS SIMULATION RESULTS (SHEET 2)

(ALL MEASUREMENTS IN METERS)

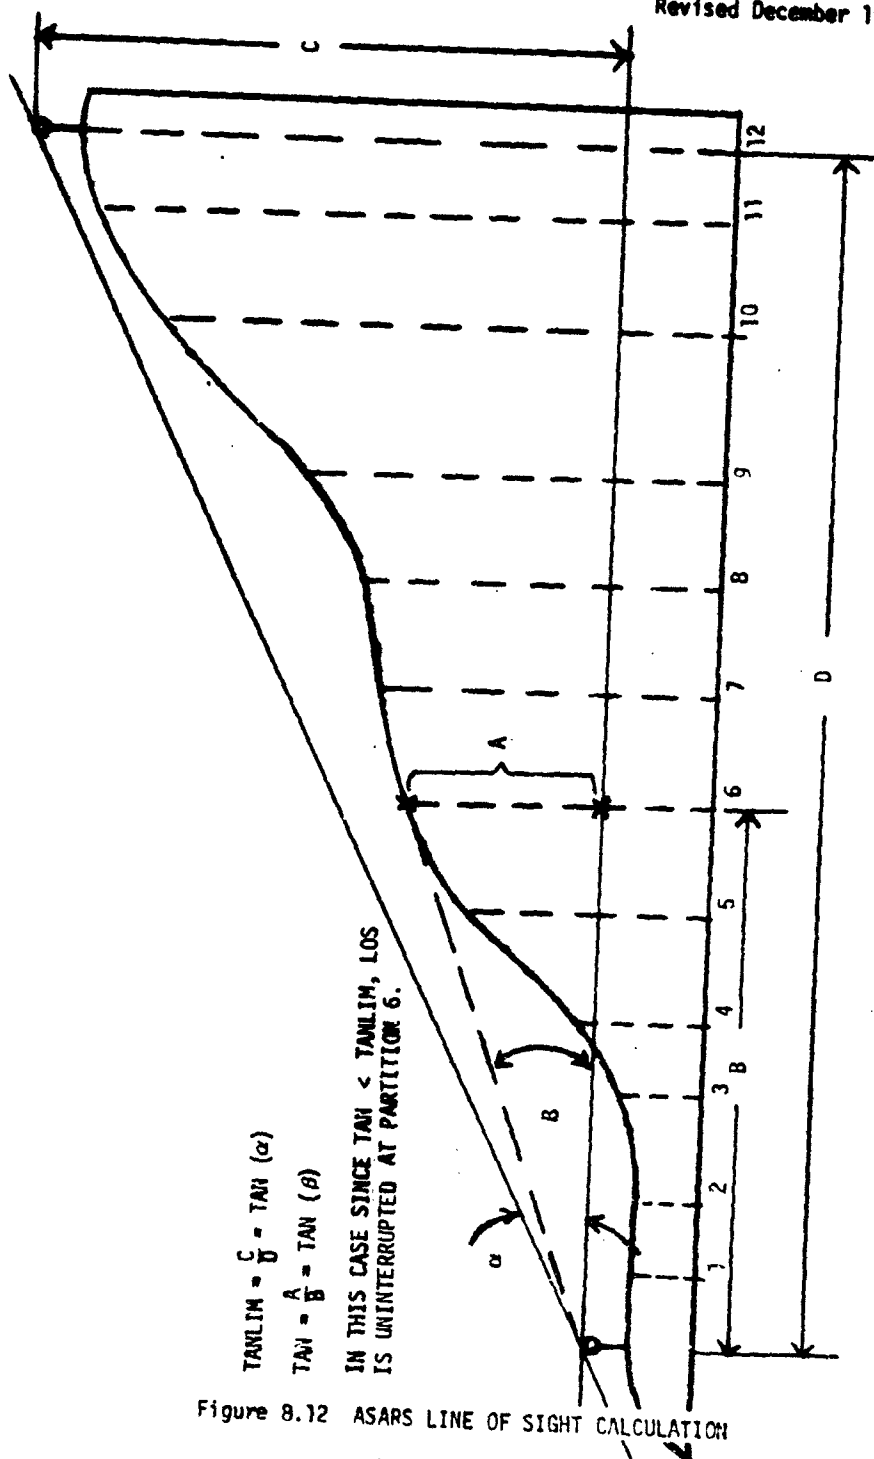

Figure 8.12 ASARS LINE OF SIGHT CALCULATION

procedure is repeated at the next endpoint.

The above procedure starts at the observer position and continues toward the target, until line of sight interruption occurs. If no interruption occurs, the fraction of target height covered by intervening macro-relief is computed.

The ASARS method of representing macro-relief along with the ASARS line of sight routine were inserted into the simulation program. Appropriate minor modifications in the simulation program were made to accommodate the change. Otherwise, the exact methodology used in the SIAF macro-relief simulation was followed for the ASARS simulation.

#### 8.7.2 Comparison

The simulation results using the ASARS macro-relief model did not compare as well as those of the SIAF simulation. The ASARS simulation produced credible results at 12.7 meters resolution. As figure 8.11 indicates, the SIAF results at this resolution were generally better than those returned by the ASARS method (though in some instances the ASARS method gave better approximations). At coarser resolutions (25.4 and 50.8 meters), the SIAF results were significantly better. In almost every instance, the SIAF simulation gave smaller errors, and thus smaller root mean square differences. Also, the ASARS simulation produced more instances where erroneous "unlimited" lines of sight were given (see figure 8.10 for explanation).

The large root mean square differences at the coarser resolutions may be attributed to the less accurate scheme for approximating macro-relief. Interpolated values in the SIAF model use data from all four surrounding grid points, whereas the ASARS model use only three of the four data points available. In addition, the ASARS relief model has the disadvantage that the choice of which grid square diagonal to use in forming the two triangular planes must be held constant throughout the entire gridded area under consideration. This disadvantage results in a loss of realism (this method does not give a unique representation of relief). A situation depicted in figure 8.13 illustrates this disadvantage. In both case 1 and case 2, the same set of four data points is input. Suppose case 2 is the desired approximation (ridge), but because positive diagonals (lower left corner to upper right corner) was the established choice of diagonal orientation, we

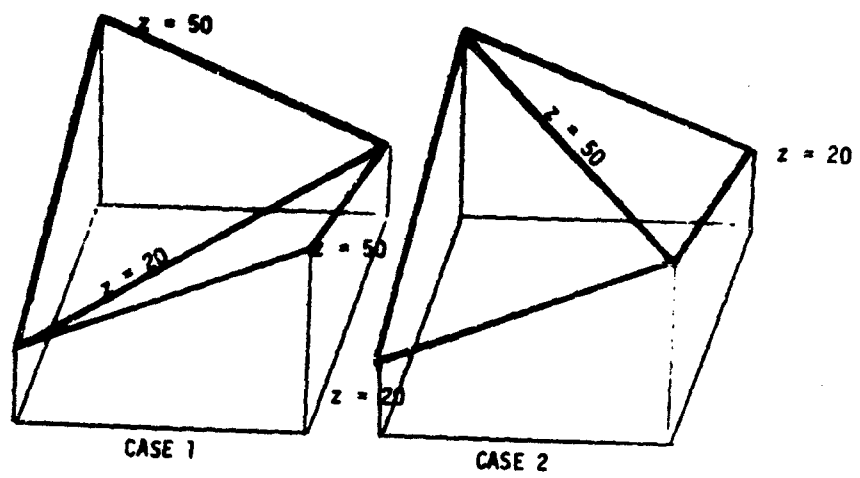

Figure 8.13 Non-Unique Terrain Surface Representation

20660-6002-R0-00

Page 8-30

Revised December 1973

obtained an inaccurate representation (ravine). Clearly, the two surfaces resulting are quite different depending on the choice of diagonals. Thus, in comparison, it appears that the two-triangular-plane method of ASARS requires a smaller grid size to represent macro-relief to the same resolution as the four-point continuous surface scheme of SIAF.

## APPENDICES

Included herein are Appendix A, Block Data Generator Program and Appendix B, Specification Statement Punch Program (SPECPN) User's Guide.

These Appendices describe two computer programs which were originally written for the IBM 7094. These programs have recently been modified to run on the IBM 360, and in the process an additional change has been made.

The main external difference in the programs is that BLKGEN no longer punches a BLOCK DATA subprogram which must be input to SPECPN. The necessary information is written on tape and is read back directly into the necessary COMMON blocks for SPECPN. This eliminates the need for two separate passes through the machine, since the two programs can be run as one single program. They can, however, be run as separate phases if necessary, using a previously generated tape as input to SPECPN.

The conversion to the 360 was handled in this manner for several reasons:

1. It eliminated the need for unnecessary card handling associated with a punched BLOCK DATA.
2. It eliminated the need for two separate passes through the machine, since there is no need to compile a BLOCK DATA subprogram, and thus improved turnaround.
3. It improved the running time of the program by eliminating the punching of the BLOCK DATA.

The inputs to both BLKGEN and SPECPN remain unchanged from those described in Appendix A and Appendix B. The 360 version can thus be run using existing decks with no modifications. However, since the programs have been combined utilizing a short driver, an additional control card is necessary to specify whether BLKGEN, SPECPN, or both are to be executed. This control card must precede all other data. Card column 1 is punched non-zero if it is desired to execute BLKGEN; card column 2 is punched non-zero if it is desired to execute SPECPN.

The appropriate column is punched zero or left blank if it is desired to skip execution of either program. The standard input decks follow this card, with no separation between BLKGEN and SPECN inputs, if both are being run. The output will be identical to that of the 7094 version, with the exception of a punched BLOCK DATA.

### I. History:

Because many large programs use COMMON quite extensively, it has become a common practice to set up all the variables of a program, equate them to blocks, and put all the blocks in a COMMON array. In order to use the variables in a subroutine, one would have to write COMMON, DIMENSION, and EQUIVALENCE cards for each variable. It soon became apparent that it would be desirable to be able to generate these COMMON, DIMENSION, and EQUIVALENCE statements by some external means. The Specification Statement Punch Program (SPECPN)<sup>1</sup> fulfills this desirability, but it requires a rather complicated BLOCK DATA sub-program to be written by the user to describe all the variables in COMMON.

The BLKGEN program was written to generate this BLOCK DATA sub-program from input cards which are easily written and changed. The combination of the BLKGEN and SPECPN programs allow an easy way to create and update a master COMMON of blocks and variables. By using these two programs, it should be fairly easy for one to generate the COMMON, DIMENSION, and EQUIVALENCE cards for each subroutine.

## II. Usage:

For a picture of the organization and the usage of the BLKGEN and SPECN programs, look at Section V. It can be seen that the usage of the two programs requires two passes on the computer. On the first pass, the master input cards are input to the BLKGEN program. The output of the BLKGEN program is the BLOCK DATA sub-program punched on cards. The BLOCK DATA sub-program is input with the variable names for each subroutine to the SPECN program on the second pass. The second pass output are the COMMON, DIMENSION, and EQUIVALENCE cards which are directly placed into the respective subroutines.

Since the specific usage of the SPECN program is given in the SPECN User's Guide, the only additional required information is the format of the input cards to the BLKGEN program. There are nine different cards accepted as input to the BLKGEN program, and each is described below:

### 1. IDENT Card:

The IDENT card is always the first card input to a run. The word IDENT starts in c.c. 1 and the number of cards that are to follow the IDENT card to describe the job is punched in c.c. 30. If c.c. 30 contains a 3, then there are three cards which contain information describing a run.

Example:

c.c. 1

IDENT

c.c. 30

1

THIS IS A SAMPLE RUN

The information punched on the card(s) following IDENT appears as comments in the BLOCK DATA program generated by BLKGEN. Columns 1 - 71 may be used for the comments cards.

### 2. PROGRAMMER Card:

The PROGRAMMER card simply contains identification information concerning the programmer, and it is always the second control card in a run following IDENT and the comment cards specified by IDENT. The word PROGRAMMER starts in c.c. 1, and the programmer's name follows immediately after (one space is skipped). Up to 24 characters may be used for the PROGRAMMER name.

**Example:**

|            |                |
|------------|----------------|
| c.c. 1     | c.c. 12        |
| PROGRAMMER | J. Gerry Purdy |

**3. DATE Card:**

The DATE card must always be the third control card in any run. The word DATE starts in c.c. 1, followed by a blank, followed by the date.

**Example:**

|        |                |
|--------|----------------|
| c.c. 1 | c.c. 6         |
| DATE   | November, 1966 |

Following the IDENT, PROGRAMMER, and DATE control cards are the cards which actually describe the COMMON blocks of the user's program. Each COMMON block is described separately in the following way:

- a) The actual cards which define the COMMON block of interest are presented to BLKCEW.
- b) Each master variable name of interest from the above defined COMMON block is denoted followed by a series of control cards identifying the variables within the master variable, their dimension, and their relative position within the block.
- c) After all master variables have been described a signal is given (ENDCOM) and the next COMMON block is defined. Following the last COMMON block definition a signal is given (ENDJOB) terminating the job. Each control card will now be described.

**4. COMMON Card:**

The COMMON control card must be the first card of each COMMON set. The number of cards that are to follow is placed in c.c. 30. What follows is the card or cards which define the COMMON block exactly as they would be punched for the user's program.

**Example:**

|        |         |
|--------|---------|
| c.c. 1 | c.c. 30 |
| COMMON | 2       |

COMMON/VSTR/BLK(50), B(6), ~~10(36)~~  
1 c.c.

In this example, cards are used to define the COMMON block VSTR. BLKGEN constructs a card image of these COMMON statements and places it in the FMT array in the output BLOCK DATA cards for processing by SPECN.

Only 1 COMMON block name (e.g. VSTR) may be defined per use of COMMON. Subsequent COMMON entries would be used if the user has more than 1 COMMON block in his program. Blank or labeled COMMON blocks are acceptable. A maximum of 9 cards may be used for each COMMON block definition.

5. M Card:

The M card identifies the block name under the current COMMON. The M is placed in c.c. 1, the block name (up to 6 characters) starts in c.c. 10, and the description of the block (up to 24 characters) starts in c.c. 40.

**Example:**

|        |         |                    |
|--------|---------|--------------------|
| c.c. 1 | c.c. 10 | c.c. 40            |
| M      | BLK1    | FLOATING CONSTANTS |

Sets of M and subsequent V cards may be repeated for each block in the current COMMON. The order in which the blocks are processed from the COMMON cards is arbitrary and the descriptions given starting in c.c. 40 are optional.

6. V Card:

The V card is the variable card and contains information about the variable which is contained within the current block. The V is in c.c. 1, the variable name (up to 6 characters) starts in c.c. 10, the dimension, if any, ends in c.c. 30, and the description of the variable (up to 24 characters) starts in c.c. 40, (optional). Singly dimensioned variables are indicated by placing a "1" or blank in c.c. 30.

**Example:**

|        |         |         |   |
|--------|---------|---------|---|
| c.c. 1 | c.c. 10 | c.c. 30 | c.c. 40                                   |
| V      | CGMR    | 10      | GM RATIO OF E, M, S, V, M, S, J, TO EARTH |

**7. JUMP Card:**

The JUMP card allows spaces to be skipped in the current block for perhaps future expansion. The word JUMP begins in c.c. 1 and the number of spaces to be skipped ends in c.c. 30.

**Example:**

|        |         |
|--------|---------|
| c.c. 1 | c.c. 30 |
| JUMP   | 20      |

The above card would cause a "hole" of 20 cells to be made in the current COMMON block.

**8. ENDCOM Card:**

The ENDCOM Card is simply a signal to the program that the current COMMON block is finished. The ENDCOM starts in c.c. 1.

**Example:**

c.c. 1  
ENDCOM

Following the ENDCOM card is either a new COMMON card or the ENDJOB card.

**9. ENDJOB Card:**

The ENDJOB card is simply a signal to the program that the inputs are finished. It is always the last card in a job.

**Example:**

c.c. 1  
ENDJOB

III. Sample Inputs:

On the following pages is a listing of a sample set of input cards to the BLKGEN program. No labeled COMMON was used in this case, although both labeled and blank COMMON will work.

## COMMON VARIABLES IN ALPHABETICAL ORDER

| VARIABLE NAME | COMMON PSN | DIMENSION SIZE | Y | DEFINITION | BLOCK NAME |
|---------------|------------|----------------|---|------------|------------|

APPENDIX B  
SPECIFICATION STATEMENT PUNCH PROGRAM  
(SPECPN)  
User's Guide

SPECN USERS GUIDE

The SPECN (SPECification statement Pulch) program was written to aid the FORTRAN programmer in his preparation of COMMON, DIMENSION, and EQUIVALENCE statements. It was designed primarily for programs which use the philosophy of master COMMON blocks and EQUIVALENCE variables e.g.

```
COMMON/COMMON/BLK1 (100), BLK2 (5000)
```

```
EQUIVALENCE (BLK1 (26), VAR1), (BLK2 (63), VAR2)
```

In this example only the variables VAR1, VAR2 are needed from the 100 cell block BLK1 and the 5000 cell block BLK2. Using EQUIVALENCE statements to identify only those variables actually used in a subroutine significantly reduces the card volume for a subroutine and the size of the symbol table necessary at compile time. This technique is opposed to the standard one of stringing out the actual COMMON variable names in the COMMON statement e.g.

```
COMMON/COMMON/ A, B, C(3), D, E, F(16), G(2), VAR1
```

To use SPECN one must supply input in two forms. First, a BLOCK DATA subprogram must be prepared containing a map of the master COMMON blocks including a complete map of each variable in COMMON, EQUIVALENCE numbers, and DIMENSION. This BLOCK DATA subprogram is then compiled and submitted as part of the SPECN job. Unless the COMMON map changes, the BLOCK DATA subprogram need never be altered again. The second input to SPECN is data cards specifying by subroutine those variables defined in COMMON. These variables may be in blank COMMON or any of the labeled COMMON blocks defined in the BLOCK DATA subprogram. The output from SPECN is the COMMON, DIMENSION, and EQUIVALENCE statements necessary for each subroutine.

The advantages of using SPECN are several:

- a) The format of the punched cards is uniform. This makes the program listing neat and easy to read.
- b) Once the BLOCK DATA subprogram has been verified for accuracy, the worry of mis-equivalencing a COMMON variable is ended.
- c) If significant changes are made in the COMMON map of a large scale program such that the equivalence numbers are disturbed, only the BLOCK DATA subprogram need be re-keypunched. The data cards used with the old COMMON may be re-submitted with SPECN to recover all the COMMON, DIMENSION, and EQUIVALENCE statements for the new COMMON map.

#### BLOCK DATA Input to SPECN

The BLOCK DATA subprogram must contain the following four labeled COMMON blocks:

```
COMMON/ISIZE/ISIZE
COMMON/BLK /BLK(I)
COMMON/FMT /FMT(J)
COMMON/XMCOM/XMCOM(ISIZE)
```

COMMON/ISIZE/ISIZE

ISIZE is an integer which defines the size of XMCOM. ISIZE will be  $3 * N$ , where N is the total number of COMMON variables defined in the users program.

COMMON/BLK /BLK(I)

BLK is a dimensioned array which contains the name of each master COMMON block in BCD. The order of the names within BLK is arbitrary.

If the following COMMON statements appeared in the user's program:

```
COMMON/ / BLK1(100), BLK2(5000)
COMMON/COMA/ABLK1(50), ABLK2(25), ABLK3(500)
```

the master COMMON block names BLK1, BLK2, ABLK1, ABLK2, ABLK3 must appear in BLK, left adjusted, in BCD. For example:

```
COMMON /BLK/BLK(5)
DATA (BLK(I),I= 1,5) /6HABLK2 ,6HBLK1 ,6HABLK3 ,
16HBLK2 ,6HABLK1 /
```

could be used to define /BLK/ for this program. The labeled COMMON block names, i.e. COMA, are not specified within BLK.

COMMON / FMT / FMT(J)

FMT is a dimensioned array defining the COMMON statements that appear in the user's program. All the information in FMT is in BCD. Since the format of a COMMON statement is so arbitrary (is it blank COMMON, or labeled COMMON; how many variables etc.) and the elements of the card so variable, the user is required to store in FMT the actual FORMAT statement that would cause the COMMON statements defined in the users program to be punched. For example; the COMMON card

COMMON /COMNAM / BLK1(100), BLK2(5000)

could be punched with the following statements

WRITE (12, 901)

901 FORMAT(6X,34HCOMMON/COMNAM/BLK1(100),BLK2(5000))

What goes into the array FMT is exactly what the compiler would generate in core at location 001: the BCD equivalent of what follows the word FORMAT, each character from " (" to the terminating ")" inclusive. In this example:

```
COMMON /FMT/FMT(7)
DATA (FMT(I),I=1,7) /6H(6X,34,6HHCOMMON,
16HN/COMN,6HAM/BLK,6H1(100),6H,BLK2(,6H5000))//
```

would be used to load the array FMT. Each COMMON statement is specified in the above manner, in any order within FMT. If the final BCD word for a given format is not a full 6 characters, fill out the word with blanks following the ")". Since each "FORMAT" must begin in a new word within FMT.

COMMON/XMCOM/XMCOM(1024)

XMCOM is an N x 3 array stored singly subscripted by rows. (N is the total number of COMMON variables in the user's program). In column 1 of XMCOM is placed the name of each COMMON variable, left adjusted, in BCD. Column 2 of XMCOM contains integer code words of the form  $I * 10000 + J$ . I is the entry in BLK which identifies the master COMMON block name appropriate for this variable. J is the equivalence number of the given variable within the master COMMON block. Column 3 of XMCOM contains integer code words of the form

$K = 10000 + L$ .  $L$  is the dimension of the given variable. (Non-dimensioned variables are indicated with  $L = 1$ )  $K$  is the entry in  $FMT$  of the first word of the "FORMAT" statement which identifies the COMMON statement containing the given master COMMON block name. A sample XNCOM will now be constructed from the following COMMON map:

```
COMMON//BLK1(24)
COMMON/COMA/ABLK1(50)
EQUIVALENCE      (BLK1 ( 1),CAE ),(BLK1 ( 2),TEMP )
1,(BLK1 ( 12),CBE ),(BLK1 ( 13),CDAYMN)
DIMENSION TEMP(10),CDAYMN(12)
EQUIVALENCE      (ABLK1 ( 1),NPR ),(ABLK1 ( 2),NDPR )
1,(ABLK1 ( 3),MATRIX)
DIMENSION MATRIX(48)
```

To compute  $ISIZE$ , we simply count the number of COMMON variables:

CAE, TEMP, CBE, CDAYMN, NPR, NDPR, MATRIX... 7

$ISIZE: 3 * 7 = 21$

COMMON/ISIZE/ISIZE

DATA ISIZE /21/

The entries in  $BLK$  will be the master COMMON block names:

BLK1, ABLK1

COMMON / BLK / BLK(2)

DATA (BLK(I), I = 2) / 6HBLK1 , 6HABLK1 /

The  $FMT$  array would be constructed from the following FORMAT statements:

```
FORMAT(6X,1,6HCOMMON//BLK1(24))
FORMAT(6X,1,6HCOMMON/COMA/ABLK1(50))
COMMON/FMT/FMT(2)
DATA (FMT(I), I=1,4) /
16H(6X,16,6HCOMMON,6HN//BLK,6H1(24)) /
DATA (FMT(I), I=5,9) /
16H(6X,21,6HCOMMON,6HN/COMA,6H/ABLK1,6H(50)) /
```

XMCOM would look as follows:

```
COMMON/XMCOM/XMCOM(21,
EQUIVALENCE (XMCOM,IXMCOM)
DIMENSION IXMCOM(21)
DATA (XMCOM(I),I= 1,21) /
16HCAE , 10001, 10001,
26HTEMP , 10002, 10010,
36HCBE , 10012, 10001,
46HCDAYMN, 10013, 10012,
56HNPR , 20001, 50001,
66HNDPR , 20002, 50002,
76HMATRIX, 20003, 50048/
```

- ① VARIABLE NAME
- ② BLK ENTRY
- ③ EQUIVALENCE NO.
- ④ FMT ENTRY
- ⑤ CONNECTION

For compatibility with the G.E. computer, XMCOM should be set

up as follows:

```
DATA (XMCOM(I),I= 1,21,3) /6HCAE ,6HTEMP ,6HCBE ,6HCDAYMN
1,6HNPR ,6HNDPR ,6HMATRIX/
DATA ((IXMCOM(I),IXMCOM(I-1)),I= 2,20,3)/
1 10001, 10001,
2 10002, 10010,
3 10012, 10001,
4 10013, 10012,
5 20001, 50001,

6 20002, 50002,
7 20003, 50048/
```

#### DATA CARD Input to SPECN

The BLOCK DATA subprogram described above contains the complete definition of each COMMON block in the users program. The remaining inputs to SPECN are a series of fixed format data cards describing the individual COMMON variables defined in each subroutine in the users program. The data cards have the following format:

For each subroutine:

##### Card 1

Contains the subroutine name in columns 1 - 6.

This card serves to identify the routine which the punched and printed output from SPECN belongs.

The name punched in cc 1 - 6 may be any combination of alphanumeric characters except ENDSUB or ENDJOB.

Cards 2-(N - 1) Contains the COMMON variable names, punched up to 12 per card, in columns 1 - 6, 7 - 12, 13 - 18, etc. The variable names must be left adjusted in each field.

Card N Contains ENDSUB in columns 1 - 6. The entry ENDSUB indicates to SPECN that all the variables for this subroutine have been entered. Columns 7 - 72 of this card are ignored.

The above series of cards are repeated for as many subroutines as desired. Following the final ENDSUB card must be placed a card with ENDJOB to indicate the end of the input data. See figure 1 and appendix for an example of the deck set-up and data card samples.

#### Output from SPECN

SPECN delivers both printed and punched output. The first block of printed output will be the XMCOM array after having been algebraically sorted about column 1. For each subroutine name card in the data deck, a message is printed stating:

THE FOLLOWING CARDS ARE FOR SUBROUTINE XXXXXX

This card is also punched. Next will be the EQUIVALENCE, DIMENSION, and COMMON cards, in that order. Continuation cards are indicated with an E in column 6 for EQUIVALENCE and a D in column 6 for DIMENSION. A card image is printed and punched. In the event that a variable is requested in the data deck that does not appear in XMCOM, the following error message is printed only:

ERROR - XXXXXX NOT IN XMCOM.

#### Operating Notes

One point that should be noted is the flexibility which results from the use of the FMT array in the BLOCK DATA subprogram. As was explained above, SPECN simply executes a WRITE (12, FMT(I)) in order to punch the Ith COMMON statement. In theory then, the user can direct

**SPECFN** to punch any card, in any arbitrary format for any arbitrary subroutine. For instance the user could place in **FMT** the necessary control characters to cause comments cards to be punched before or after **COMMON** statements, which define the variables in that **COMMON** block. Another use of **FMT** might be to include **DIMENSION** card images for those variables which are multi-dimensioned in the user's program since there is no provision in **XMCOM** for indicating such.

This could be accomplished as follows:

- a) Place in **FMT(J)** the **FORMAT** statement that would cause the desired **DIMENSION** statement to be punched.
- b) In the appropriate column 3 entry in **XMCOM**, set the dimension of the multi-dimensioned variable to 1.
- c) Instead of pointing to the **COMMON** card image in **FMT** for this variable, point to the **DIMENSION** card image, **J**.
- d) Be sure that another variable in the subroutine list does point to the proper **COMMON** card image.

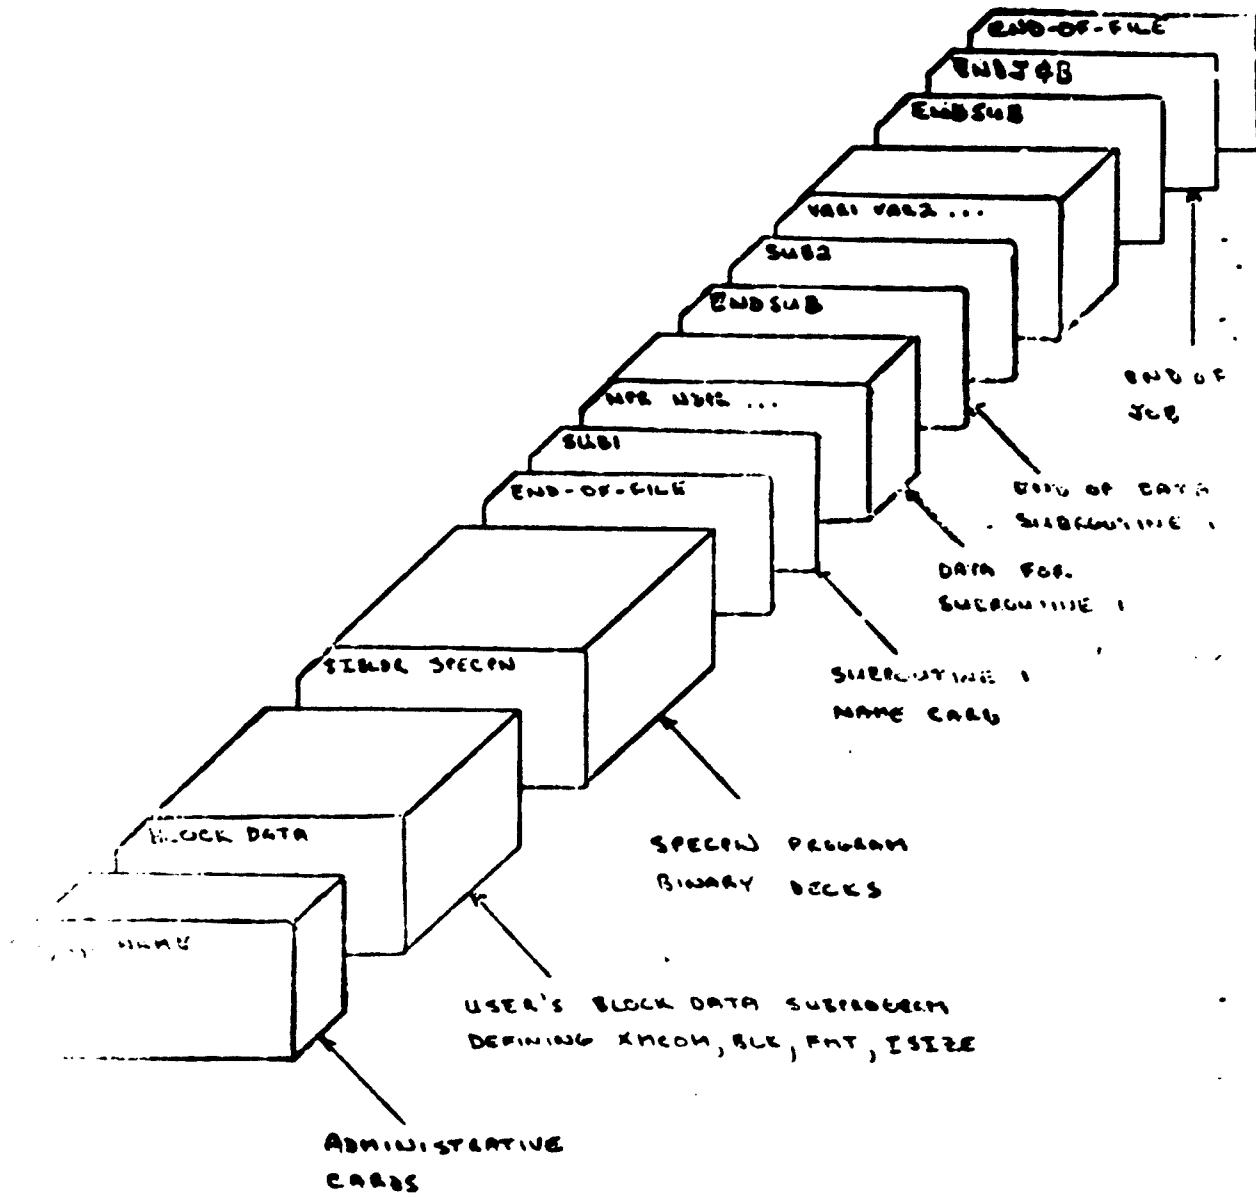

Setting the dimension to 1 will suppress the punching of a standard **DIMENSION** card.

To aid the spot checking of **EQUIVALENCE** variables it is a good practice to list the variables in ascending **EQUIVALENCE** order on the data cards for each subroutine. If it is desired to obtain **EQUIVALENCE** listing by master **COMMON** block, that is, have **SPECFN** start with a new **EQUIVALENCE** card for each new master **COMMON** block, it is only necessary to break up the variables by **COMMON** block within a subroutine and submit each set under the name of the same subroutine. The fact that the subroutine name is repeated within the data deck is immaterial since it is used only for identification of the output.

The following restrictions should be observed when running **SPECFN**:

- a) The total size of **XMCOM** + **BLK** + **FMT** must not exceed 22,753<sub>10</sub> cells. This is based on the **SPECFN** version currently in use on the 7094.

- b) Do not use a subroutine card with ENDSUB or ENDJOB in columns 1 - 6. These variables may appear on a data card providing they are not placed in columns 1 - 6.
- c) No variable name may be repeated in XMCOM.
- d) When operating on the 7094, a PUNCH card should be included in the administrative cards if more than 500 punched cards are expected or if it is desired to have the punched cards listed and/or interpreted.

SPECN DECK SETUP - FIGURE 1

The following page is an example of the data card  
input to SPECPR
